A house is available. The appointment is for one year in the first instance, and may be renewed for a further year, and will become vacant on April 21, 1952. Applications, giving age, nationality, qualifications, present and previous appointments (with dates), together with names and addresses of three referees, should be sent to the Secretary, Sheffield Regional Hospital Board, Fulwood House, Old Fulwood Road, Sheffield, 10, to arrive not later than March 10, 1952. (8375)

Psychiatry—contd.**SHEFFIELD, MIDDLEWOOD HOSPITAL**
Sheffield Regional Hospital Board

Applications are invited from registered medical practitioners for the whole-time post of

REGISTRAR (Psychiatry)

to the above hospital, which is a recognized training hospital for the D.P.M. Residential accommodation is available. Applications, giving age, rationality, qualifications, present and previous appointments (with dates), together with names and addresses of three referees, should be sent to the Secretary, Sheffield Regional Hospital Board, Fulwood House, Old Fulwood Road, Sheffield, 10, to arrive not later than March 10, 1952 (8376)

BURY, FAIRFIELD GENERAL HOSPITAL
(Comprising 175 Mental, 203 Chronic and 133 Obstetric and Gynaecological beds)

Bury and Rossendale Hospital Management Committee

Applications are invited for the post of **JUNIOR HOSPITAL MEDICAL OFFICER** at the above hospital. This post is mainly for the mental and chronic sick beds, and the successful applicant will be required to work in the main under the direction of the Consultant Psychiatrist. Salary will be at the rate of £700 per annum, rising by annual increments to £1,000 per annum. Conditions of service in accordance with national recommendations. Applications should be made to the undersigned—H. Wilkinson, Secretary to the Committee, Bury General Hospital, Walmsley Road, Bury, Lancs. (8434)

PRESTWICH HOSPITAL

Prestwich, Manchester (Psychiatric—3,088 beds)

Applications are invited from registered medical practitioners, male or female, for appointment of **JUNIOR HOSPITAL MEDICAL OFFICER** (Resident or non-resident)

No accommodation is at present available for a married man. All modern treatments are practised and facilities will be given for studies for higher qualifications. Opportunities for experience at out-patient clinics. Applications, giving full details of age, training and experience, together with the names and addresses of at least two referees, should be sent to the Medical Superintendent not later than Saturday, March 1, 1952 (8505)

LIVERPOOL (near), RAINHILL HOSPITAL

Rainhill Mental Hospital Management Committee

Applications are invited from registered medical practitioners, male or female, for the above post. This mental hospital of 2,800 beds provides excellent opportunities for postgraduate experience in all branches of psychiatry. All forms of modern treatment are given. Salary £670 per annum, less £150 for residential emoluments. Applications, with copies of testimonials, or names of two referees, to be sent to the Medical Superintendent as soon as possible. (8435)

OXFORD, WARNEFORD AND PARK HOSPITALS

Oxford Regional Hospital Board

Applications are invited for an appointment as

SENIOR HOUSE OFFICER

at the above hospitals. The Warneford Hospital (140 beds) is in process of development as an acute psychiatric unit, with special emphasis on postgraduate training and facilities for research. It is closely associated with the adjacent Park Hospital (a neurosis centre of 30 beds, with daily out-patient clinics) at which the successful candidate will have ample opportunities for working. Experience can thus be gained in all branches of psychiatry, including child psychiatry. The appointment, now vacant, is specially suitable for a young graduate beginning the study of psychiatry with a view to specialist training and higher qualification, and every facility will be granted for these purposes, including opportunities for attendance at other appropriate hospitals in Oxford. The clinical work and postgraduate training in the hospitals is conducted on the system of two medical firms each headed by a consultant, and the House Officer will have experience with both. Accommodation is available for an unmarried candidate, but permission to live out of the hospital, subject to the usual terms of duty, may be granted if married. Salary and conditions of service in accordance with national scales. Applications, together with copies of recent testimonials, should be sent to the Medical Superintendent, Warneford Hospital, Oxford, within fourteen days of the appearance of this advertisement. (8258)

WINTERTON HOSPITAL MANAGEMENT COMMITTEE**THREE SENIOR HOUSE OFFICERS**

Required at the above Mental Hospital. Applications, in writing, should state full name, age and qualifications, to be addressed to the Medical Superintendent, Winterton Hospital, Sedgfield, Stockton-on-Tees, within fourteen days of the appearance of this advertisement.—C. W. Gill, Secretary to the Hospital Management Committee. (8600)

RADIOLOGY**NOTTINGHAM GENERAL HOSPITAL (441 beds)**
Sheffield Regional Hospital Board

Applications are invited from registered medical practitioners possessing the D.M.R.(D.) for the post of

WHOLE-TIME ASSISTANT RADIOLOGIST

The successful candidate will work under the direction of the Consultant in charge of the department, and will be required to undertake occasional sessions at other hospitals in the Nottingham area. Salary scale £1,300 by £50 to £1,750 per annum. Application forms and further details may be obtained from the Senior Administrative Medical Officer, Sheffield Regional Hospital Board, Fulwood House, Old Fulwood Road, Sheffield, 10. Completed forms must be returned to the Secretary not later than March 22, 1952. (8389)

SCOTLAND, SOUTH-EASTERN REGIONAL HOSPITAL BOARD

Applications are invited from suitably qualified medical practitioners for the post of

ASSISTANT RADIOLOGIST in Fife

The duties are mainly in hospitals in Kirkcaldy and Dunfermline, under the direction of a Senior Radiologist. The salary of the post is on the scale £1,300 by £50 to £1,750. The post is superannuable, and conditions of service are in accordance with the regulations. Applications, giving details of age, qualifications and previous experience, together with the names of three referees, should reach the Secretary, South-Eastern Regional Hospital Board, Scotland, 11, Drumshough Gardens, Edinburgh, 3, within thirty days. (8601)

KING'S COLLEGE HOSPITAL
Denmark Hill, S.E.5

Applications are invited for the post of **REGISTRAR to the Diagnostic X-ray Department**. Candidates should hold or intend to work for a Diploma in Radiology. The post will be in the grade of Registrar or Senior Registrar, according to the qualifications and experience of the candidate selected. Applications, stating age, qualifications and experience, together with the names of three referees, should be addressed to the undersigned to arrive within four weeks of the appearance of this advertisement.—S. W. Barnes, House Governor. (8436)

LAMBETH HOSPITAL, Brook Drive, S.E.11
South-West Metropolitan Regional Hospital Board

Applications are invited for the post of **SENIOR REGISTRAR** in the X-ray Diagnostic Department. D.M.R. essential. The hospital is recognized as a training school for radiographers. Convancing will disqualify, but candidates are not precluded from visiting the hospital (by arrangement) if they so desire. For form of application apply (enclosing stamped addressed envelope) to the Secretary, Lambeth Group Hospital Management Committee, Renfrew Road, S.E.11, to whom the completed applications should be returned by March 1. (8332)

BRISTOL, UNITED HOSPITALS
(Joint appointment with the South-Western Regional Hospital Board)

Applications are invited by the above Boards from registered medical practitioners for the joint appointment of **REGISTRAR in Radiology (Diagnostic)**. The appointment will be subject to the terms and conditions of service of hospital medical and dental staff negotiated between the Minister and the profession. The successful applicant will be appointed to work in the first instance for one year in the United Bristol Hospitals, the teaching hospital for Bristol University. Applications, stating age, qualifications, experience and giving the names of two referees, should be sent not later than March 10, 1952, to Secretary to the Board, Royal Infirmary Branch, Bristol, 2. (8467)

MANCHESTER REGIONAL HOSPITAL BOARD

Applications are invited for the post of **SENIOR REGISTRAR (in Diagnostic Radiology)** to the Withington, Wythenshawe and Baguley Hospitals, Manchester.

D.M.R.D. essential. Forms of application may be obtained from the Senior Administrative Medical Officer, Manchester Regional Hospital Board, Cheetham Road, Manchester, 8, and should be returned, with the names of three referees, to be received by March 10, 1952. (8437)

COUNTY MEDICAL OFFICER OF HEALTH
at a salary of £2,450 per annum, rising by three annual increments of £100 to £2,750 per annum. Candidates must possess the qualifications prescribed by the Local Government Act, 1933, have wide knowledge and experience of the duties of a Medical Officer of Health and possess sound administrative and organizing ability. Full particulars of the appointment may be obtained from my office, and completed applications should reach me by March 5, 1952. Canvassing, directly or indirectly, will be a disqualification.—K. Tweedale Meaby, Clerk of the County Council, Shire Hall, Nottingham. (8351)

SWANSEA, COUNTY BOROUGH OF

Applications are invited from duly qualified medical practitioners for the post of

ASSISTANT MEDICAL OFFICER (Female)
Applicants must have had postgraduate resident hospital experience and should be under 45 years of age unless already holding a similar superannuable appointment. Salary £850 by £50 to £1,150 per annum. Application forms may be obtained from the Medical Officer of Health, Public Health Department, The Guildhall, Swansea, to whom they should be returned not later than Monday, February 25 1952. Canvassing, either directly or indirectly, is a disqualification.—T. B. Bowen, Town Clerk, The Guildhall, Swansea. (8206)

SURREY COUNTY COUNCIL

Applications are invited from registered medical practitioners for several permanent superannuable full-time appointments of

ASSISTANT COUNTY MEDICAL OFFICER
Applicants should possess a Diploma either in Public Health or Child Health. Main duties will be in connexion with school health and maternity and child welfare services, but officers appointed will be required to undertake such other public health work as may be allocated to them by the County Medical Officer. Salary £850 per annum, rising by annual increments of £50 to £1,150 per annum. The appointments will be subject to the successful candidates passing a medical examination, to the provisions of the Local Government Superannuation Act, 1937, as modified by the National Health Service (Superannuation) Regulations, and to the staffing regulations of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice. Candidates should note that the Council can give no assistance in finding housing accommodation. Applications, stating age, qualifications and experience, together with a copy of three recent testimonials, and/or the names of three referees, should be made on the prescribed form and sent to the County Medical Officer, Kingston-upon-Thames, by March 8, 1952.—T. W. W. Goodridge, Clerk of the Council. (8576)

WORCESTERSHIRE COUNTY COUNCIL
ASSISTANT COUNTY MEDICAL OFFICER
with Additional Public Health Duties

Applications are invited from registered medical practitioners (men or women) for the above whole-time post. The duties will chiefly concern school health and child welfare services. The possession of the D.C.H. or the D.P.H. and experience in connexion with infectious diseases will be of advantage. The salary and conditions of service will be in accordance with the recent award of the Industrial Court, i.e., £850 per annum, rising by annual increments of £50 to £1,150. Past experience will be considered in fixing the starting point within the scale. The successful candidate must own and drive a car. The holder of this appointment (now vacant) also acted as occasional Deputy at the Hayley Green Isolation Hospital and to the Medical Officer of Health for the boroughs of Halesowen and Stourbridge, for which additional payment is made. The appointed officer will be considered for all or any of these additional appointments. The post is superannuable, subject to medical examination and determinable by three months' notice. Applications, on forms to be obtained from the County Medical Officer, County Buildings, Worcester, should be returned to him by February 29, 1952.—W. R. Scurfield, Clerk of the County Council (X42). (8272)

WORCESTERSHIRE COUNTY COUNCIL
BOROUGH OF OLDBURY
OLDBURY BOROUGH MEDICAL OFFICER OF HEALTH AND WORCESTERSHIRE COUNTY DIVISIONAL MEDICAL OFFICER AND SCHOOL MEDICAL OFFICER

Applications are invited from qualified and duly registered medical practitioners, men or women, holding the Diploma in Public Health and possessing the requisite experience. The salary will range from a minimum of £1,491 13s. 4d. to a maximum of £1,858 6s. 8d. (namely the Borough Medical Officer of Health post will be on the scale of £516 13s. 4d., rising by annual increments of £16 13s. 4d. to a maximum of £583 6s. 8d., and the Divisional Medical Officer post on the scale £975 by annual increments of £37 10s. to a maximum of £1,275 per annum). The post is superannuable, subject to medical examination and determinable by three months' notice. The successful candidate will be required to reside in the Divisional Area. He will be required to undertake such duties as may be assigned to him and will be precluded from undertaking any other duties except with the Council's previous consent. Travelling allowance for the use of the officer's own car will be paid in accordance with the County scale. Application forms from County Medical Officer, County Buildings, Worcester, to be returned not later than March 12, 1952.—Kenneth Pearce, Town Clerk, Municipal Buildings, Oldbury; W. R. Scurfield, Clerk of the County Council, Shirehall, Worcester. (X104). (8606)

YORK, CITY OF, EDUCATION COMMITTEE
School Medical Service

Applications are invited from male registered medical practitioners for the permanent post of

ASSISTANT SCHOOL MEDICAL OFFICER
Applicants must have been qualified for at least three years and will be required to devote their whole time to the duties of the office. Preference will be given to those who have had special experience of diseases of children. The salary offered, in accordance with the terms of the Industrial Grade Award No. 2285 (Public Health Service), is £850 per annum, rising by annual increments of £50 to £1,150 per annum. The appointment will be subject to the Local Government Superannuation Act of 1937 and to the passing of a medical examination. Form of application and conditions of appointment may be obtained from the undersigned on receipt of a stamped addressed envelope and should be returned within three weeks of the appearance of this advertisement.—H. Oldman, Chief Education Officer, Education Offices, 5, St. Leonard's Place, York. (8607)

ADMINISTRATIVE**KIDDERMINSTER, BLAKEBROOK HOSPITAL**
Mid-Worcestershire Hospital Management Committee

Applications are invited from registered medical practitioners for the post of

MEDICAL OFFICER
for two sessions per week, to be responsible for the medical administrative work of the hospital; this is allowed for in the sessions. The successful candidate will have the care of all chronic sick in the hospital (220 beds) and will undertake weekend responsibility on a rota basis. The appointment is initially for a period of twelve months, but, subject to a review of the scheme, the holder will be eligible for re-election. The appointment is subject to the terms and conditions of hospital medical and dental staff and the remuneration is at the rate of £175 per session per annum. Further particulars can be obtained from the undersigned, to whom applications, giving details of age, qualifications and experience, should be addressed not later than Monday, March 10, 1951.—C. M. Smith, Secretary, Mid-Worcestershire H.M.C., Birmingham Road, Bromsgrove, Worcs. (8412)

EIRE

ST. ANNE'S HOSPITAL
Northbrook Road (Leeson Park), Dublin
Applications are invited for the post of **Whole-time RADIOTHERAPEUTIC REGISTRAR** Non-resident appointment. Experience in radiotherapy essential. Higher qualification an advantage. For applicants unable to provide own transportation at this time, arrangements can be made for loans to be deductible from the monthly honorarium paid by the hospital. Student visa only necessary. Address, Administrator. (7271)

AUCKLAND HOSPITAL BOARD, N.Z.
Applications are invited from those with the necessary qualifications for the status of Junior or Senior Specialist for the position of
RADIOLOGIST, Board's Institutions
Applicants must be qualified medical practitioners of the British Commonwealth, and the appointee shall be registered in New Zealand before taking up duty. Salary, Junior Specialist £1,260 per annum, rising to £1,560 per annum by annual increments of £50. Senior Specialist £1,660 per annum, rising to £1,910 per annum by annual increments of £50. Commencing salary within these scales will be in accordance with qualifications and experience in the specialty. The amounts quoted are in New Zealand currency and are living out rates. Living accommodation is not provided. Particulars regarding payment by the Board of travelling expenses are set out in the conditions of appointment which, together with an application form, may be obtained from the Office of the High Commissioner for New Zealand, 415, Strand, London, W.C.2. Applications, addressed to the Secretary, close at the office of the Board, Kitchener Street, Auckland, New Zealand, at noon on Monday, April 7, 1952. (8487)

UNIVERSITY OF OTAGO, Dunedin, New Zealand
RALPH BARNETT CHAIR OF SURGERY
The University of Otago proposes to appoint a
PROFESSOR OF SURGERY
to take up office in January, 1953. Salary £2,560 per annum. Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 5, Gordon Square, London, W.C.1. Applications close on April 15, 1952, in London and New Zealand. (8610)

HER MAJESTY'S COLONIAL RESEARCH SERVICE
Applications are invited from medical practitioners with qualifications registrable in the United Kingdom for two posts of

MEDICAL RESEARCH OFFICER
in the Virus Research Institute, Lagos, Nigeria
Experience in virus techniques and/or medical research an advantage. Institute has well-equipped laboratory and good accommodation is available for married or single officers. Selected candidates will be required to undertake research in laboratory and in the field on animal or human virus diseases and to co-operate in general programme of research, e.g. by assisting in collection of specimens and animals required for virus research, etc., and to supervise and perform when necessary routine tests on vaccine or sera. Every assistance possible will, however, be given to enable officers to carry out individual programmes of research. Salary according to age and experience in the scales £565 by £35 to £740, £795 by £35 to £1,005, or £1,075 by £50 to £1,270 plus overseas research allowance at following rates: £290 per annum on salary below £830; £330 on £830 to £1,005; £290 on £1,070; £260 on £1,120 to £1,270 per annum. A temporary cost-of-living allowance at rate of ten per cent of basic salary is at present payable. If Government quarters are provided a rent of not more than ten per cent of salary (maximum £150) would be charged. Outfit allowance £60. Free passages provided for selected candidate and his wife and for children up to thirteen years. Superannuation provided under Colonial Superannuation Scheme. Forms of application obtainable from Under Secretary of State, Colonial Office (Research Department), Sanctuary Buildings, Great Smith Street, London, S.W.1, and further information regarding Institute and nature of duties from Director of Colonial Medical Research at same address. (8484)

UNIVERSITY OF SYDNEY
Applications are invited for the following positions.

SENIOR LECTURESHIP IN PHARMACOLOGY

TWO LECTURESHIPS IN OPERATIVE DENTISTRY

ONE LECTURESHIP IN PROSTHETIC DENTISTRY

The above vacancies mainly arise from a decision to establish permanent lectureships in place of temporary or part-time appointments. Salaries will be within the range of: Senior Lecturers, £A1,050 by £A50 to £A1,300; Lecturers, £A650 by £A50 to £A1,000 with the addition in all cases of cost-of-living adjustment. Salaries will be subject to deductions under the State Superannuation Act. The commencing salaries will be fixed according to the qualifications and experience of the successful candidates. Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 5, Gordon Square, London, W.C.1. The closing date for the receipt of applications is March 3, 1952. (8572)

HER MAJESTY'S COLONIAL SERVICE, Malaya

Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom with one or more years' experience after qualification are required for appointment as

MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH

for General Medical and Health duties

Appointment is available (a) on probation for permanent establishment; (b) on employment from the National Health Service; and (c) on short-term contract with gratuity. (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale 1952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). Note. Doctors with more than one year's approved experience after age 25 (including service in Her Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g., F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malaya salary on leaving Malaya at the end of their engagements. Emoluments as under (a), including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a), including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity refer to doctors eligible for expatriate terms under Malayan Regulations (i.e., those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan Medical Service. The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates, which are lower than the rates in the United Kingdom. Government quarters with heavy furniture are provided at a low rent, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/242/51). (5187)

HER MAJESTY'S COLONIAL SERVICE
Gold Coast

TWO SPECIALISTS (Ear, Nose and Throat Specialist and Anaesthetist Specialist)

Required in the Medical Department, Gold Coast. The first to form and take charge of ear, nose and throat departments in the larger hospitals, the second principally to train local staff in anaesthesia. Appointments can be made on a permanent basis with pension (non-contributory) on retirement (the normal age of retirement is 50), or on short-term contract with gratuity on satisfactory completion of service. Candidates in the National Health Service may resign from the National Health Service but retain their superannuation rights during their time in the Gold Coast (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Gold Coast salary on leaving the Gold Coast at the end of their engagement. Salary for either post is £1,700 per annum (£1,300 per annum pensionable basic salary plus £400 per annum pensionable expatriation pay). Pension is earned at the rate of 1/600th of the final pensionable emoluments for each completed month of service. The gratuity for contract service is payable on completion of the contract at the rate of £150 per annum. A temporary cost-of-living allowance of £195 per annum is also payable to officers whether on permanent or contract terms. Free passages are provided for officer, wife and up to three children under nine years, on first appointment and on leave. Annual local leave is permissible and generous home leave is granted after each tour of eighteen months. Quarters are provided at rental of £150 per annum. Income tax at local rates. Social and recreational amenities are good. Applicants for the post of ear, nose, and throat specialist must possess at least the F.R.C.S. Applicants for the post of Anaesthetist Specialist must possess a Diploma in Anaesthetics. Application forms can be obtained from the Director of Recruitment (Colonial Service), Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/321/52). (8608)

UNIVERSITY COLLEGE HOSPITAL OF THE WEST INDIES, Jamaica, B.W.I.

Applications are invited for ten posts of House Officers in the new University College Hospital:

FOUR HOUSE SURGEONS
for General and Surgical duties

THREE HOUSE SURGEONS

THREE HOUSE PHYSICIANS

for Casualty and Out-patient duties

The appointments will be for one year commencing June 1, 1952. Each House Officer will serve four months in the surgical, medical and casualty departments respectively. Salary (£350 per annum, less £100 in respect of board, residence, etc. Return first-class passages by sea will be paid. Applications should be sent to the Hospital Manager and Secretary, University College Hospital, Mona, St. Andrew, Jamaica, B.W.I., before March 31. (8485)

BEER YAACOV, near Tel Aviv

Applications are invited for the post of

ANAESTHETIST

for 500-bed chest hospital at Beer Yaacov, fifteen miles from Tel Aviv. A new hospital possessing modern thoracic surgical unit. Applicants should hold Diploma of Anaesthetics and must have experience in anaesthesia of the thoracic surgery. Training of junior anaesthetist part of duties. Contract minimum one year. Salary £1,500 to £1,800 annually, according to experience. Free passage for the successful applicant, his wife and children up to the cost of three adult fares as well as personal effects. Return passage paid after completion of contract. Full board and married quarters provided at low cost. Appointment subject to satisfactory medical examination. Applications, stating age, family status, experience and three references, to Medical Department, Malben, P.O.B. 2883, Tel Aviv. (8486)

UNIVERSITY APPOINTMENTS

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

Hyde Park Corner, London, S.W.1

Applications are invited for

TWO LECTURESHIPS

one in Pathology and one in Bacteriology

Salary scale £900 to £1,100 per annum, with superannuation and family allowances. Applications should be sent in to the Professor of Pathology by Saturday, March 8, and should be accompanied by the names of two referees. (8589)

UNIVERSITY OF LONDON

The Senate invite applications for the
CHAIR OF MEDICAL PROTOZOLOGY
tenable at the London School of Hygiene and Tropical Medicine. Salary will range from £2,250 to £2,750 a year. Applications (ten copies) must be received not later than April 1, 1952, by the Academic Registrar, University of London, Senate House, W.C.1, from whom further particulars should be obtained. (8573)

University Appointments—contd.

UNIVERSITY OF LONDON KING'S COLLEGE

Will require on April 23, 1952, a
LECTURER IN PHYSIOLOGY
on the Junior Lecturer scale of £600, rising by annual increments of £50 to £750, with family allowances and F.S.S.U. benefits. Particulars and application forms should be obtained from the Registrar, King's College, Strand, W.C.2, whom completed applications should reach by March 22. (8588)

UNIVERSITY OF BELFAST

Applications are invited for a
LECTURESHIP IN PREVENTIVE MEDICINE
in the Department of Social and Preventive Medicine in the Queen's University of Belfast. Salary £1,300 by £50 to £1,750, plus provision for superannuation. In certain conditions the salary may rise to £2,000. Initial placing on the scale will depend on experience and qualifications. Applications should be received by March 30, 1952. Further particulars may be obtained from G. R. Cowie, M.A., LL.B., Secretary. (8611)

UNIVERSITY OF LEEDS

Department of Obstetrics and Gynaecology
Applications are invited from registered medical practitioners who are members of the Royal College of Obstetricians and Gynaecologists and who hold a Surgical Fellowship for the newly instituted post of
READER IN OBSTETRICS AND GYNAECOLOGY
at a salary on the scale £1,500 by £100 to £2,000 a year, initial salary according to qualifications and experience. Applications (fifteen copies), together with the names of three referees, should reach the Registrar, The University, Leeds, 2 (from whom further particulars may be obtained), not later than March 17, 1952. (8612)

NOTICES

APPLICANTS ARE ADVISED NOT TO SEND original testimonials when replying to advertisements. Copies will answer the purpose quite as well, and in the event of their being lost or mislaid no inconvenience will ensue.

Assistance with M.D. Thesis. Prospectus, list of tutors, etc., on application to Dr. G. E. Oates, University Examination Postal Institution, 17, Red Lion Square, London, W.C.1. Phone: HOLborn 6313

RHEUMATIC DISEASES (WEEK-END). ALL day Saturday and Sunday, March 29 and 30. Rheumatic Unit, St. Stephen's Hospital. Apply Fellowship of Postgraduate Medicine, 60, Portland Place, London, W.1. Langham 4266.

SURGICAL REVISION (F.R.C.S.). MONDAY, Thursday, and Friday mornings. March 10 to April 26. Royal Cancer Hospital. Apply Fellowship of Postgraduate Medicine, 60, Portland Place, London, W.1. Langham 4266.

TUBERCULOSIS EDUCATIONAL INSTITUTE

A three-day Clinical Course will be held at the Red Cross Sanatoria of Scotland (Tor-na-Dee and Glen o'Dee) on March 19, 20, and 21. Fee £3 3s. Applications to the Secretary, Tuberculosis Educational Institute, Tavistock House North, Tavistock Square, London, W.C.1. (8488)

UNIVERSITY OF LONDON

Applications are invited for the Geoffrey E. Duveen Travelling Studentship for 1952-53, value £650, for research in any aspect of oto-rhino-laryngology. Further particulars and forms of application (to be received by April 30, 1952) may be obtained from the Academic Registrar, University of London, Senate House, W.C.1. (8591)

SITUATIONS VACANT

North Devon Hospital Management Committee.—Pathological Laboratory, Bouthport Street, Barnstaple. —Applications are invited for the post of Technician or Junior Technician in a new laboratory serving the North Devon District. Considerable experience in haematology is essential. Salary and conditions in accordance with Whitley Council scales. Applications, stating age, qualifications and experience, together with the names of two referees, to the Pathologist at the above address. (8108)

PHARMACISTS,
DIETITIANS, DISPENSERS, NURSES
AVAILABLE

Dispensing Assistant (Indy), with Apothecaries' Hall Certificate, seven years' hospital experience, free immediately for locum duties.—Box 634, B.M.J.

Dispenser-Bookkeeper requires post with doctor or doctors in large mixed practice. London, Brighton, or near districts.—Box 708, B.M.J.

RECEPTIONISTS, SECRETARIES,
TYPISTS, ETC.
VACANT

None of the advertisements in these columns relates to a man aged 18-64, or a woman aged 18-59 inclusive, unless he or she is excepted from the provisions of the Notification of Vacancies Order, 1952, or the vacancy is for employment excepted from the provisions of that Order, unless an individual advertisement indicates otherwise.

Help in comfortable house and small modern Hampshire surgery. Educated girl secretarial, simple laboratory and nursing. Family life, three children under nine.—Box 741, B.M.J.

RECEPTIONISTS, SECRETARIES,
TYPISTS, ETC.
AVAILABLE

The Notification of Vacancies Order, 1952, provides that the services of any advertiser under this heading may be engaged only through the medium of the Local Employment Exchange or approved Employment Agency, unless he or she is over the age of 64 or 59 respectively, or otherwise excepted from the provisions of that Order.

Capable doctor's widow, experienced but no direct qualifications, good appearance, pleasing personality, 40, urgently desires position secretary, receptionist.—Box 744, B.M.J.

Doctor's widow, ex-nurse, seeks position with doctor as Receptionist-Housekeeper. Unfurnished accommodation for self and adult son essential. London.—Box 726, B.M.J.

Experienced secretary/shorthand typist, London hospital nursing experience, seeks post W.1 area.—Miss Lose, 23, Cumberland Drive, Esher.

Highly recommended doctor's Secretary, disengaged, London. Quick, accurate shorthand-typist. Used responsibility.—Box 719, B.M.J.

Lady, 25, experienced doctor's secretary/steno-grapher, requires post, consultant or general practitioner.—Box 743, B.M.J.

Married couple, housekeeper caretakers, seek post, experienced. Our own furniture. Good references.—Box 745, B.M.J.

Part-time Receptionist, S.E.A.N., ophthalmic certificate, filing, typing.—Nancy Hall, 9, Southwood Lawn Road, N.6.

Secretary, used medical work, four years' experience, including literary work, seeks post, London, resident or non-resident.—Box 742, B.M.J.

Secretary desires post, London area, experienced medical and psychiatric work. Good French, German.—Box 636, B.M.J.

Applicants requiring testimonials, theses, copied or duplicated should communicate with Manton Secretarial Service, Ltd., 98, Victoria Street, S.W.1 (Victoria 0141), who are specialists.

General Practitioners. Your tedious paper work, correspondence, accounts, etc., dealt with at economic hourly rates by fully experienced, reliable Secretary specializing medical work. Available at your convenience for occasional/regular, short/longer periods, also evenings and Saturdays. Own typewriter.—Mary Simon, 58, Heath Street, N.W.3. Telephone mornings: HAM 5216.

Secretaries, Receptionists, Domestic Helps carefully selected to suit your requirements.—International Service W.F.I. (Brigadier and Mrs. James), 157, Ebury Street, S.W.1. SLO 1359, 2059.

Thoroughly trained Medical Secretarial staff may be engaged through Brook Street Bureau, Ltd., 59, Brook Street, W.1, Gro. 6666, and 2, George Street, Croydon. Phone: 3363.

CONSULTING ROOMS, ETC.
AVAILABLE

Consulting Rooms available in good house in Harley Street. Rents from £300 per annum, inclusive. Full service.—Apply Elliott, Son and Boyton, 86-7, Wimpole Street, W.1, WELbeck 8367, or Waite and Waite, 36, Cavendish Square, W.1. MAYfair 4912.

Queen Anne Street. Excellent part-time Consulting Room, central heating, plate on door. Rent £100. Free March 25.—Apply Box 619, B.M.J.

Readers frequently desire to refer to advertisements concerning appliances, preparations, etc., which have appeared in earlier issues of the *Journal*.

The Advertisement Manager can supply particulars at any time.

In dealing with written enquiries, especially from overseas, correspondents are, wherever possible, put in direct contact with the advertisers in whose products they are interested.

HOTELS

CORNWALL.—TREHARROCK MANOR AND FARM. Jersey herd. Log fires. Spring is here. Golf St. Enodoc. Trout and salmon. Near Polzeath (surf-bathing), Lundy Bay, Port Quin and Port Gaverne.—Port Isaac 234.

DEVON.—BOVEY HOUSE, BEER. GUESTS welcomed in this historic Manor House, 1½ miles from fishing village of Beer. Brochures sent on request. Branscombe 241.

HANTS.—BOURNEMOUTH. THE HIGHCLIFFE for a warm welcome. 100 centrally heated rooms mostly facing sea full south. Short stay 33s., 36s. per day inclusive. Weekly terms 8 to 10 gns. 40 private bathrooms at 6s. A. M. Wild (late Cairo and Zurich). Bournemouth 7210 and SLOane 9191.

SOUTH DEVON.—DUNMORE HOTEL, Shaldon, standing in seven acres of secluded gardens, with unrivalled sea views. Private suites, sun lounges, magnificent ballroom, En-Tout-Cas, tennis court, boating, bathing, fishing, golf. Licensed, excellent cuisine. Special diets if required.—Tel.: Shaldon 250/251. Main line railway station, Teignmouth.

SUSSEX.—ROYAL VICTORIA HOTEL, St. Leonards-on-Sea. 5½ gns. weekly inclusive, October to May in this first-class, A.A. 4 star R.A.C. hotel.

CRUISES

Cruising and Dingy Sailing holidays in craft from 8 ft. to 78 tons. Instruction if required. All accommodation afloat. Proper shipboard comfort. Island Cruising Club and Sailing School, Islcombe, Devon.

TOURS

Conducted Parties: April 7 to 19, Swiss and Italian Lakes, 39 gns. June 16 to 28, Innsbruck, marvellous Dolomites and Zurich, 42 gns. June 30 to July 12, Kiental, Zermatt; Saas-Fee, 39 gns. July 15 to 26, Nr. Interlaken, Susten Pass, Lucerne Lake, 34 gns. (or to July 29). July 30 to August 12, lovely Engadine and Val Bregaglia, 41 gns. August 15 to 29, Austria, Glarus, Brunnen on Lucerne Lake, 40 gns. September 1 to 13, Montreux, Chamonix (Nr.) Fribourg and Berne. Apply C.T.U., (Est. 1913, Dr. Fothergill), Chorley Wood, Herts.

MOTOR CARS, HIRE, ETC.

Saloon car wanted, popular make, medium horsepower, good appearance, £100 to £350.—Martin, 20, Addiscombe Grove, Croydon, Surrey.

Priority Motor Repairs Service for members of the medical profession. Mechanical and coachwork repairs, recellulosing, lubrication service and valeting. Free collection and delivery within three miles' radius for repairs costing £2 10s. or more.—Mann Egerton & Co., Ltd., 68, York Way, King's Cross, N.1. Tel.: TER 7772. (Two minutes' walk King's Cross underground and main line stations.)

8-h.p. or 10-h.p. Car, as new as possible, required at once.—Morley, 54, Streatham Hill, London, S.W.2. Tulse Hill 4489.

MISCELLANEOUS

Wanted: Hanovia U.V. Lamp with or without infra-red. State model, number, year, and price required.—95, Richmond Road, Kingston-on-Thames.

Cambridge Cardiograph, in perfect condition, for mains and battery, for sale.—LAN. 1361.

For Sale. Milne Murray's Axis Traction Forceps, £10. Minnitt's Gas-air apparatus with cylinder, £14. Flushing Curette, 10s.—Box 747, B.M.J.

For Sale. McCarthy resectoscope, Kidd's diathermy cystoscope, child's examination cystoscope.—Box 706, B.M.J.

Mahogany Pedestal Desk, best workmanship, 4 ft. 6 in. by 2 ft. 6 in., £37 10s. Mahogany Bookcase 6 ft. 3 in. by 3 ft. 9 in., £25.—(Evenings), 6, Westwood Court, Woodside, Wimbledon.

Bronze Name Plates with cream enamel lettering. Send size and lettering for estimate.—Osborne, 117, Gower Street, London, W.C.1.

Bulbs from Holland. Descriptive catalogue of gladioli, begonias, etc., sent free on application.—John Voges, Jr., P.O. Box 28, Hillegom, Holland.

Electric Sterilizers, £5 15s. Combined Ophthalmic Sets, Sphygmomanometers, Syringes, at wholesale prices.—Medical Equipment, "Medeq."—60, Duke Street, London, W.1.

Microscopes. Highest prices paid for good modern types. Send or bring your equipment for valuation.—Wallace Heaton, Ltd., 127, New Bond Street, W. (May 7511).

NURSING HOMES

FOR SALE

South Croydon. Charming detached nursing home. Excellent position. Every modern convenience, 6 bedrooms, 3 reception rooms, sun parlour, cloakroom, vestibule, kitchen, scullery, bathroom, w.c. Detached garage (2 cars). Excellent gardens (½ acre): Freehold £6,750 (including antique and modern furnishings). Full details from Killick and Knight, 8, Station Road, S.E.25. (LIVINGSTONE 1864).

HOMES

CHEADLE ROYAL, CHEADLE, CHESHIRE

A registered Hospital for MENTAL DISEASES, and its Seaside Branch, GLAN-Y-DON, Colwyn Bay, N. Wales. The object of this Hospital is to provide the most efficient means for treatment and care of Patients of both Sexes suffering from MENTAL and NERVOUS DISEASES. The Hospital is governed by a Committee appointed by Trustees. Deep and Modified Insulin Coma; E.C.T. and Psychotherapeutic treatment given. VOLUNTARY, TEMPORARY, AND CERTIFIED PATIENTS RECEIVED. For terms and further information apply to the Medical Superintendent. Telephone: Gatley 2231.

THE HERMITAGE, Twyford, Berkshire

A REGISTERED NURSING HOME, within easy reach of London, for the treatment of alcoholic and drug addiction and the neuroses. Modern methods. Restful country-house atmosphere. Private rooms from 8 gns. a week. Apply Secretary, Twyford 53. Interviews in London. Welbeck 4523, if desired.

THESE WILL HELP YOU

Hyperacidity: gentle two stage control

- (1) *Immediate neutralization of excess acid
and prompt relief from pain.*
- (2) *Prolonged adsorption and gradual neutralization
of any further acid secreted.*

Alimex is a pleasantly flavoured colloidal preparation of aluminium hydroxide with magnesium hydroxide. It corrects gastric hyperacidity, relieves gastro-intestinal irritation and is a valuable adjunct in the medicinal treatment of peptic ulcer.

Alimex acts without liberating carbon

dioxide so that there is no risk of acid rebound.

After the administration of Alimex the stomach contents remain sufficiently acid to permit normal digestion to proceed without interruption.

Bottles of 8 fl. oz. and in bulk for dispensing purposes.

ALIMEX

ANTACID ADSORBENT

Literature, samples and further information from the Medical Department
BOOTS PURE DRUG COMPANY LIMITED NOTTINGHAM ENGLAND

ST16

Aci-jel

is available in 3 oz. tubes. On original prescriptions specify "Aci-jel with applicator."

combats vaginitis by restoring vaginal acidity

in non-specific vaginitis

Aci-jel rapidly controls symptoms, discourages pathogens and favours re-establishment of normal flora.

in recurrent vaginitis

Aci-jel—used before, during and after menses—largely prevents recurrences.

after vaginal surgery

healing is hastened and symptoms controlled by Aci-jel, a highly buffered acid (pH 4.0) vaginal jelly. In a recent comparative study* Aci-jel showed

- "the best maintenance of vaginal acidity"
- "a good Döderlein response"
- "complete symptomatic relief"
- "patient comfort was outstanding"

ULCER
THERAPY**

AN EFFECTIVE METHOD of relieving the symptoms of hyperchlorhydria and peptic ulceration is provided by Collubarb Tablets, containing aluminium hydroxide (Collumina brand) 5 grains (0.32 gm.) phenobarbitone $\frac{1}{4}$ grain (0.016 gm.) and atropine sulphate $\frac{1}{500}$ grain (0.13 mg.).

A Three-fold Function

- 1 *The aluminium hydroxide neutralises excess acid without producing an alkaline condition of the stomach.*
- 2 *The phenobarbitone helps to relieve the anxiety tension so often associated with hyperchlorhydria and peptic ulceration.*
- 3 *The small dose of atropine sulphate moderates excessive motor activity of the gastro-intestinal tract with diminution of secretion of gastric juice.*

Cartons of 24 and 100 (film wrapped) Containers of 500

Quick, deep, prolonged sleep

It is well known that no single barbiturate combines quick action with gentle, prolonged sedation. In Carbrital capsules, however, rapid onset is obtained by the inclusion of pentobarbitone sodium, while the use of carbromal, a mild sedative, has the effect of maintaining profound, normal sleep for up to eight hours. There are little or no after effects. Carbrital is indicated in *all types* of insomnia and as a general sedative.

CARBRITAL

FOR ALL TYPES OF INSOMNIA

STUDIES ON THE PHYSIOLOGY OF AWARENESS: ANOXIA AND THE LEVELS OF SLEEP*

BY

J. W. LOVETT DOUST, M.B., B.Sc., M.R.C.P.

AND

ROBERT A. SCHNEIDER, M.D.

(From the Department of Medicine, Cornell University Medical College; and the New York Hospital, New York, U.S.A.)

It has recently been suggested (Lovett Doust, 1951a) that the varying strata of attention and awareness are intimately related to the levels of the arterial blood oxygen saturation as determined by the methods of continuous oximetry. It was shown that "attention peaks" of periods of increased concentration and awareness are associated with a rise in the oxygen saturation levels, whereas periods of boredom, decreased concentration, reverie, etc., are correspondingly accompanied by falls in the oximetric values.

Considerable work has already been done on the question of anoxia in various pathological and pharmacological analogues of natural sleep, and its importance in these states appears to be paramount. An impressive parallelism has also been found between many types of fatigue conditions and the clinical syndrome induced by experimental anoxic anoxia; indeed, Barcroft (1925) suggested many years ago that the symptomatology of chronic anoxia was that of mental and bodily fatigue.

These phenomena are closely associated with consciousness, and it was therefore thought desirable to follow such changes to their logical fulfilment—namely, that of natural sleep.

Experimental Procedure

Seven normal healthy human subjects were studied and 22 observations made over a period of three months. Six of the subjects were males and the seventh a female. Ages ranged from 22 to 36 years.

Arterial blood oxygen saturation levels were measured photo-electrically and continuously by means of a Millikan oximeter (Millikan, 1942), with the sensitive photo-cell attached to the pinna of the ear in the conventional manner. The instrument was previously standardized on each occasion by the inhalation of 100% oxygen from a cylinder through a modified B.L.B. mask for at least seven minutes until stationary readings were obtained on the galvanometer.

The experiments were conducted under conditions as natural as possible and, so far as circumstances permitted, for night-long periods. For the latter experiments the subject changed into night attire, performed the customary chores of brushing his teeth—reading if that were his wont preparatory to his retiring—and was provided with a comfortable bed in the darkened laboratory.

An observer was constantly present in the same room and a continuous record was made of the galvanometric deflections as they occurred. He also noted changes in the position of the subject, the type and rate of respirations, snoring, the influence of external stimuli, the apparent depth of sleep, etc. At the conclusion of each experiment an inquiry was made of the subject to ascertain details of the depth and quality of sleep, the ability to recall events of the night, and the nature of any fantasy or dreaming.

An attempt was made objectively to record respiratory pattern changes, but this was not found feasible under the otherwise "natural" conditions of the investigation. It was abandoned in view of the already large body of data in this regard (Best and Taylor, 1945).

Results: Sleep and Progressive Anoxaemia

A rather consistent pattern was seen to obtain in some seven observations of protracted, restful, satisfactory sleep. Five observations were made over a period of about three to six hours, from 1 a.m. to 7 a.m. Four observations were made earlier in the evening—for example, from 10 p.m. to 1 a.m.—and the remainder during a postprandial "nap" from 1 to 2 o'clock in the afternoon.

The accompanying Table lists the basic data, and oximetric charts are exemplified in Figs. 1, 2, and 3. Considerable variation was noted to occur, both between different subjects and in repeated observations on the same subject, but a similar overall picture was evident. Noteworthy points will be mentioned later concerning the differential progress of the march of sleep, but, in general, it may be said that the subject began on a base-

*This work was done during the tenure of a Nuffield Foundation Medical Fellowship (J. W. L. D.) and of a Commonwealth Fellowship (R. A. S.).

"T" is time in minutes spent in any one plane of sleep; "O₂" is the % range of arterial blood oxygen saturation as determined by continuous oximetry; "M" is the number of observed gross movements made by the subject; "N" is the number of possibly disturbing noise stimuli; "R" the number of gross changes in respiratory response patterns.

line level of arterial oxygen saturation which was always within the critical limits of normality—that is, between 92 and 98% oxygen—and that this base-line tended to be at its lowest when fatigue was at its maximum.

From the point at which the light was quenched and the subject composed himself for sleep, oxygen levels fell progressively in a step-like fashion, with fluctuations of 1 to 3%, to reach their consistent and now unvarying minimum of about 87% oxygen at the period of deepest sleep. This was maintained for about 30 minutes, after which the oxygen level would increase, again slowly step by step, until awakening occurred. Furthermore, it was found repeatedly that the period between 4 and 5 a.m. was the time at which anoxaemia was at its greatest and "life was at its lowest ebb."

The Levels of Sleep

Most investigators have divided the varying depths of the sleep pattern into a series of arbitrary levels—reminiscent of the planes of anaesthesia. For our purpose it seemed practicable to distinguish seven such planes of sleep: (1) A period of wakefulness in which conversation is possible and the subject, although at physical rest, still responds to external stimuli by conscious attention. (2) A period of pre-sleep in which muscular relaxation is greater than in plane 1, fantasy life is enriched, drowsiness is obvious, and periods of dozing and transitory lack of awareness are common. The subject often feels some sensations of floating and depersonalization; subjective warmth permeates his body. (3) A period of light sleep in which objective response to stimuli occurs but is relatively unconscious, considerable muscular activity being present as further progressive relaxation of the many muscle groups is sought. (4) A period of heavy deep sleep in which little muscular movement is apparent, no response to external stimuli takes place and the subject is "dead to the world." Wakefulness, in like fashion, is a reversal of the process of sleep and its passage contains a similar number of stages starting with deep sleep, although the time intervals are somewhat displaced. Plane 5 is the period of light sleep following deep sleep; plane 6 the period of pre-wakefulness; and plane 7 the actual awakening to the new world of to-morrow.

Thus we have a series of seven planes of sleep, from wakefulness to wakefulness once more. An average of our observations suggests that anoxaemia is differentially distributed in each of these planes in the following manner:

Plane 1:	Wakefulness	..	Artl. oxygen satn.	=96%
" 2:	Pre-sleep	..	" "	=90-92%
" 3:	Light sleep	..	" "	=89-91%
" 4:	Deep sleep	..	" "	=87-88%
" 5:	Light sleep follow- ing deep sleep		" "	=89-91%
" 6:	Pre-wakefulness		" "	=90-92%
" 7:	Awakening	..	" "	=92-98%

These seven planes of the sleep cycle were selected arbitrarily in accordance with the judgment of the observer and the subsequent inquiry of the subject. The oxygen levels, it should be noted, are means and tend to be relative to the initial base-line of the subject. One in whom high initial levels are recorded may drop by similar amounts to one in whom an initially relatively low base-line is seen. But it is by no means uncommon, on the other hand, for a precipitous fall to take place from an initial high base-line to the same anoxaemic level of 87%.

Significance of Muscular Movements in Sleep

A study of our protocols reveals some interesting information regarding the twists and turns, shifts in position, limb movements, and certain quasi-purposeful hand movements noted during these sleep observations. These are briefly considered.

(A) *Influence of Posture, etc.*—Because of the necessity that the oximeter earpiece should not come in contact with the pillow, the subjects were instructed that they could lie prone, supine, or on one side or the other, but that the decision regarding which side must be made before the standardization of the oximeter. Their motivation was apparently excellently maintained even during unconsciousness, for none attempted to turn to the side on which the oximeter had been fixed; indeed, most stated that they customarily lay on the one side or the other, but rarely on either.

It was noted that after some turning, usually from the side to the supine position and back again during plane 2, the subject would settle on his side and fall asleep in plane 3 in that position. By the time plane 4 had been reached, however, the subject was usually on his back, and would commonly complete his period of deep sleep thus.

Interestingly enough, exact temporal correlation with the oximeter record showed that each change in position was meaningful in terms of the blood oxygen saturation levels. Not only were twists and turns and changes of position associated with considerable oximetric fluctuations, but also such fluctuations preceded the muscular movement. The saturation levels, for example, would begin to fall from 92 to 91%, and such a fall would be immediately followed, in planes 2 or 3, by muscular movement; if the fall were a major one—for example, to 90%—then often it would immediately be followed by a change in position from side to back, or vice versa. In like fashion such a change in position, apparently occasioned by an incipient anoxaemia, would be followed by a rise in the oxygen saturation levels—for example, from 90 up to 92-93%.

If the subject was not disturbed by this and hence brought into a lighter plane of wakefulness, a third happening would then occur—that is, the oxygen saturation would again fall, not merely to its previous low level, but well beyond it, such a sequence often presaging an imminent change from a lighter to a deeper plane of sleep. Indeed, it was often found to be possible not only to estimate the exact plane of sleep by the saturation value recorded on the oximeter, but also to predict the ensuing pattern of sleep from the combination of the changing oximetric values and the concomitant muscular movements.

(B) "*Pruritic*" Phenomena.—A rather constant observation during the passage of the subject from plane 2 to plane 3 was his tendency to scratch or rub his face or body. Usually this manipulation was confined to the face, nose, and neck; not uncommonly, however, it would spread and include the genital area or, indeed, anywhere else on the body surface. The activity proved on inquiry to be at a very low level of conscious awareness, but sometimes it might of itself induce a slight increase in awareness, and the subject would then be conscious of what he was doing. It formed a useful landmark of the depth of sleep and the immediate progress which might be anticipated. The meaning of the phenomenon is discussed later.

Respiratory Responses During Sleep

Plane 1 is characterized by irregular activities such as yawning, coughing, and sighing. These are fully conscious but involuntary. They accompany subjective feelings of tiredness, lethargy, and fatigue, and help to condition the subject for the sleep awaiting him. Oximetrically, each activity is invariably preceded by anoxaemia and usually succeeds in temporarily overcoming this. Apart from these activities little of significance was noted during the observation of planes 1 and 2 and 6 and 7 in this respect. Subjectively, however, it was not uncommon to be told by an introspective sleeper that he was aware of certain other

Fig. 1.—Male subject "C." Composite chart showing results of clinical observation and those of continuous photoelectric oximetry during 1½ hours of sleep. See text for description of the seven levels or "planes" of sleep. In this and in subsequent charts the initial reading of 100% oxygen followed the preparatory inhalation of pure oxygen by facemask for standardization of the oximeter.

FIG. 2.—Female, subject "A." Restful sleep during a six-hour period of observation.

FIG. 3.—Male subject "B." Restful sleep. Illustrates differences of temporal relationships for times spent in the various planes of sleep—compare Figs. 1 and 2. Interruptions in the oximeter tracing indicate periods during which the instrument was switched off to prevent burning of the subject's ear.

changes, especially during plane 2. These consisted of periods of shallow breathing alternating with periods of apnoea and deep breathing. They seemed to be relatively automatic, the subject being conscious that they were occurring though exercising no conscious voluntary control over them. Indeed, when such control is established these patterns tend to disappear and the passage to deeper sequences of sleep is interrupted.

Planes 3 and 4 are characteristically noisy periods of sleep; groaning, mumbling, grunting, gasping, snoring, sighing, and sometimes coughing being individually representative responses for any given subject. Each of these activities is closely correlated with oximetric changes, in a similar fashion to that observed with muscular movements; a trumpeting snore, for example, often occurs at a time when exceptionally low oxygen levels have been reached (for example, down to 85%) and seems to be an effective mechanism for returning the saturation values to their previous levels. Sometimes, as we have all observed, such snoring awakens the sleeper, the mechanism of which is readily understandable in terms of these findings.

Response to External Stimuli

Observations were recorded of all external noises occurring during the sleep experiments. Such external noise was discontinuous in pattern but continued throughout the periods of observation. It consisted of traffic noises, the sirens of tug-boats on the river, the beating of storms against the window-panes, the whine of aircraft passing overhead, the occasional clatter of dishes from another floor, the cries of sick children from the department of paediatrics across the courtyard, and finally the sometimes inadvertent, sometimes consciously produced noises of the observer at his night's vigil.

Despite the irregular discontinuity of all these stimuli the subject responded differentially to them according to the depth of his sleep. During planes 1 and 2 and 6 and 7 little change was noted oximetrically or clinically to such stimuli, the subject accepting them consciously and incorpor-

ating them into his awareness as part of the field of his environment. In planes 3 and 5, however, dramatic responses were noted. The subject at these times was not consciously aware of these discontinuous stimuli, but each time they occurred he would show a prompt if ill-sustained "attention peak," bringing his oxygen levels up by 1-2%. The significance of this in terms of the tendency for noise to bring about wakefulness is obvious. In plane 4, however, no response to noise took place, the subject remaining oblivious to the stimulus, and the oximetric values maintaining their unswerving degree of anoxaemia.

Fatigue, Wakefulness, and the Inability to Sleep

It is not always easy to fall asleep to order. Out of 22 observations, seven represented unsuccessful attempts to sleep in that no progress was made beyond plane 2 despite their being continued under apparently optimal conditions and for a period of some hours.

It would appear that more than mere physical fatigue is necessary to ensure the sleep state. According to the Pavlovian

theory a "set" is required incorporating all the usual preliminaries to sleep; but it would appear that this is inadequate of itself, since sleep was sometimes impossible even given every apparent requirement for it, including its urgent desire on the part of the subject and very considerable physical fatigue.

A typical example of this is shown in Fig. 4. The subject could get from plane 1 to plane 2 but not beyond this point. Each time his oxygen saturation level fell to 91-93% it was brought back again by such mechanisms as muscular movement, respiratory patterns of yawning, sighing, grunting, etc., and abandonment to sleep proved impossible. Interrogation of the reasons for this in all four instances proved fruitless, the subject remarking that he just could not understand his inability to fall asleep.

Some factor of emotional or mental fatigue must, it would seem, be added to purely physical factors. It is common knowledge that deep sleep is often impossible for the neurotic or the individual who cannot relax emotionally.

FIG. 4.—Two examples of inability to sink into deep sleep, despite subjective feelings of tiredness and fatigue.

Perseveration of ideas, repeated inability to forgo interest in the environment or in personal problems, persistent introspection, or anxiety is sufficient to maintain relative wakefulness, and it is possible that such factors as these, operating at the peak of their intensity in the fantasy-full planes 1 and 2, produce those patterns of relative awareness which prohibit further progress to a deeper plane.

Dozing

The "nap," "forty winks," "resting one's eyes" are expressions by which are usually indicated temporary cessations of conscious awareness occurring at times not usually associated with sleep—for example, after a heavy meal, during a monotonous conversation, on a hot afternoon, or with a relative cessation of attention-provoking external stimuli. On introspection, however, it would appear that these states are indistinguishable from natural sleep, the deficit of consciousness often appearing to telescope the subjective appreciation of the passage of time, and, furthermore, fantasy is usually enriched to a marked degree.

Oximetrixally, it was found (see Table) that these states corresponded to planes 2 and 3 and 5 and 6 of sleep, and on clinical observation could be termed states of impaired awareness. Sometimes they could be shown to proceed to the deep sleep of plane 4, but more often some degree of consciousness was present and circumstances prohibited this from happening. Sometimes, again, it seemed that the unpleasant feeling accompanying drowsiness or dozing might be due to the guilt that sleep should not have been taking place at that time at all. On such occasions retrospective analysis revealed that unpleasant affect had coloured the fantasies, the dreams, or the reverie, and had done so with all the force of the anoxia present at that time.

Discussion

The Physiological Epiphenomena of Sleep

A large body of consistent evidence testifies to a certain cycle of changes which occur during the process of natural sleep. Briefly these include the following: a decline in the blood pressure of from 10 to 30 mm. Hg systolic, with the lowest level about the fourth hour of sleep; bradycardia; reduction in the basal metabolic rate by 10–15%; hypothermia; slowing and intermittent irregularity of respiration, together with a tendency for it to be costal in character; possible disappearance of the knee-jerk, and presence of a positive Babinski sign though lowered thresholds for vasomotor reflexes are typical; oliguria; a variable effect on gastric secretion and some increase in gastric motility; finally, depression of most glandular secretions has been noted to occur.

Among the neurophysiological observations, some interesting electro-encephalographic studies have been made during the various phases of the sleep process. Lindsley (1944) has abstracted the evidence and quotes the relevant literature from Berger's (1932) original observations, showing how five stages of sleep have been delineated from this point of view. Summarizing the E.E.G. evidence, it would seem that the alpha rhythm gradually disappears in the passage from wakefulness to pre-sleep and is extinguished and replaced by 4–5 cycles a second activity in light sleep. These slow waves are complicated by spindles of 14 cycles a second activity in deep sleep, the spindles tending to disappear and the slow waves beginning to decrease in frequency and regularity as the depth of sleep progresses. Brazier (1949) has further shown that a shift occurs with sleep in the origins of maximal voltage activity from the parieto-occipital area to the prefrontal and precentral regions of areas nine and six respectively.

Now, disappearance of alpha rhythm and the production of slow activity is also characteristic of experimentally induced anoxic anoxia when this is pushed to the point of

obvious impairment of consciousness (Berger, 1934; Davis *et al.*, 1938; Gibbs and Davis, 1935), and provides us with some interesting circumstantial confirmation of our findings of anoxia in sleep.

In similar fashion all the physiological disturbances occurring during sleep noted initially in this section have also been shown to be associated with states of anoxia. As with the analogy of the E.E.G. findings so with these other disturbances, and we list this evidence for the epiphenomena of anoxia in the order in which we have mentioned them in our discussion on sleep.

Hypotension.—Anderson *et al.* (1946) found that experimental acute anoxia is often accompanied by hypotension and sometimes faintness.

Bradycardia.—The response of the heart rate to anoxia is inconsistent, but Haldane *et al.* (1919) showed that continued anoxic anoxia sometimes leads to slowing after an initial tachycardia.

Basal Metabolism.—Killick (1940) showed that in animals subjected to slow carbon monoxide intoxication the basal metabolic rate decreased, and Beck (1936) confirmed this for human subjects similarly poisoned. At high altitudes, however, such a depression of the basal metabolic rate was not found to occur in human subjects, the rate actually undergoing no change (Monge, 1937), although Hamon *et al.* (1935) showed a decreased oxygen consumption in animals under diminished barometric pressure.

Body Temperature.—Hamon *et al.* (1935) noted that the body temperature falls as the atmospheric pressure decreases. Armstrong (1939), studying human subjects taken to a simulated altitude of 12,000 ft. (3,658 m.), found consistent falls in body temperature lasting up to some 24 hours. Gellhorn (1943) also states that the body temperature falls with anoxia.

Respiration.—The depth of respiration is increased more by anoxia than is the rate (van Liere, 1942). Mosso (1898) first demonstrated the periodicity changes of the respiratory pattern at high altitudes and mentioned the tendency for mountaineers to show a Cheyne-Stokes type of breathing. "This irregularity most frequently occurs during sleep at night. It is caused by oxygen-want, as shown by the fact that the administration of oxygen abolishes it" (van Liere, 1942, p. 113). Barcroft *et al.* (1923) produced radiological evidence for the increased costality of the manner of breathing seen in natives living in the high Peruvian Andes.

Reflexes.—Jokl (1939) showed that a depression of the deep reflexes begins when ascent by man reaches an altitude of 6,600 ft. (2,012 m.) This would represent a blood oxygen saturation level of about 92%. King *et al.* (1932) showed specifically that anoxia inhibits the knee-jerk. Vasomotor reflexes are stimulated (Bouckaert *et al.*, 1941). A Babinski-type plantar response is common in the coma of hypoglycaemic shock (Lups and Kramer, 1940), and, as Gellhorn (1943) has shown, the clinical and other findings associated with hypoglycaemia parallel those of anoxia.

Urine.—Adolph (1934) found a complete anuria in frogs subjected to anoxia, the suppression being associated with total constriction of the glomerular arterioles. Van Liere *et al.* (1935) noted a diminished urine excretion in dogs subjected to anoxic anoxia. These findings have not, however, been confirmed in man.

Gastric Motility.—Anaemic anoxia in dogs greatly increased the tonus of the stomach wall and also the intensity of the hunger contractions (Carlson, 1916). Curtis and Hamilton (1938) showed that these findings are also true for patients with pernicious anaemia.

From these considerations it seems evident that the relationship between the physiological changes occurring in association with the sleep process and those of anoxia is an intimate one. We shall not press their possible functional identity further, however, for a reason which becomes evident later on.

The Biological Significance of Sleep

Philosophers from the earliest times have speculated upon the meaning and necessity of sleep, and their theories have ranged from those suggesting that the soul leaves the body and wanders freely through the world to the concept that man dies at the end of each day and is reborn with the coming of the following dawn. These theories of primitive men are echoed in the findings of contemporary dynamic psychologists who conceive of sleep and dreams as regressive patterns to an earlier plane of existence. Dreaming, says Jung for example, "is a psychosis brought about by free choice"; and Freud writes, "Dreaming is a fragment of the superseded psychic life of the child."

Physiologically, sleep has been perhaps the least well investigated aspect of the functions of man, such theories as have been advanced to account for it being crude and often purely hypothetical extrapolations reflecting the stage of medical progress at the time. The so-called "neuronal theory," postulating a retraction of dendritic processes which leads to a suspension of cortical activity, is an example of this. Various chemical theories have also been proposed, indicating lactic acid accumulation acting as a cerebral depressant, "hypnotoxin," acetylcholine, and "brom-hormone," with little supporting evidence for their role in natural sleep. The Pavlovian theory, based largely on animal experimentation, suggests that sleep is a spread of conditioned internal inhibition and seems to account for one aspect of the problem, though its connexion with such hypothalamic centres as have been shown to be involved in various pathological disturbances of the sleep rhythm appears to be remote.

Kleitman (1939) has stressed the importance of afferent impulse bombardment in relation to sleep, and has published some important work which suggests that a lessening in the number of such impulses from the muscles of the periphery is a necessary prelude to sleep. This has been further elaborated by Max (1935) into what he terms the "motor theory of consciousness."

As long ago as 1897 Howell suggested that vasomotor fatigue could explain the necessity for sleep and showed that the fall in blood pressure and peripheral vasodilatation accompanying sleep could logically accompany a relative cerebral anaemia. This theory has been criticized, but it still remains a practical possibility, for differential anoxia on a vascular basis could exist with no overall change in cerebral blood flow.

Ontogenetically, the diurnal rhythm of sleep seems to develop from an irregular polyphasic cycle in infancy, and it has often been suggested that wakefulness is a modality which depends upon maturation, that it is a state to which the organism must *ascend* at intervals and in a pattern which is unique to the individual at any one time in his development. If this is so, then it might be expected that all the forces which contribute to make up the uniqueness of individual personality also assist in the formation of the individual pattern of the sleep-wakefulness cycle.

In a review of the literature concerned with fatigue Bartley and Chute (1947) conclude that fatigue is a part of the picture of frustration and conflict, and any assessment of fatigue states—including its dimension of sleep—must take these important factors into account. They stress the ever-present nature of conflicts and point to the part these play in the constant homeostatic adjustments which the individual is called upon to make. Sleep would seem to be a release from these conflicts and a time for the "realignment" of the personality in terms of homeostatic demands. Inability to express emotional needs leads to tension development, and if this tension is abnormally great sleep becomes impossible. The tendency for emotional tension to "spread" and become "somatized" is representative of the organism's inability to withstand the impact of such self-generated forces, and is also the pattern and a means for their—usually inadequate—discharge in dreams. Mature personality development is normally sufficient to permit of

the organism's abandonment to sleep, since the force of such deviated "neurotic" tensions is not relatively great. In psychiatrically disturbed individuals, and particularly in psychoneurotics, this is not so; for them conflicts, in the face of poorly differentiated personality development, are very considerable, and sleep, because it entails relaxation, is either impossible or greatly upset.

These considerations help in understanding the often otherwise incomprehensible inability of the normal subject to get to sleep. We have seen already how physical tiredness may be urgently present, the subject apparently desirous of sleep, and all the reflex conditioning stimuli at hand, yet sleep may prove impossible. From the concepts we have just considered it would appear conceivable that these subjects were not emotionally ready for sleep; they were not in a condition to accept its psychodynamic demands. Furthermore, the inability to sleep, it would seem, postulates as well the continuance of a degree of skeletal muscular tonus inhibitory to progress in the sleep cycle. Just as, therefore, inability to sleep may entail persistently increased muscle tone, keeping up an afferent bombardment of the cortex, so also may an actual fear of sleep prevent its onset from a fear of the fantasies accompanying it.

As an example of the interactionism between our findings of anoxia and these psychodynamic considerations of the sleep process, it is interesting to reflect back to our observations of skin-scratching noted to occur in many of our subjects during their passage through plane 2 of the sleep cycle. One of the accompaniments of anoxia produced by lowered barometric pressure is a lowered threshold of irritability of the skin. This may be the result of an altered body-water distribution, as Smith (1928) suggested, and he has postulated it as one of the causes of restlessness in anoxic subjects—a concept which fits in nicely with our findings of the increase in muscular movements at this stage of sleep. It also might be expected psychodynamically in view of the considerable weight of evidence pointing to the function of the skin as an erogenous zone from which pleasure may be obtained through stimulation. The unconscious preference shown by the subjects for those areas of the skin especially sensitive in this respect—for example, the naso-oral mucous membrane, the cheeks, neck, and genitalia—lends support to these considerations.

The psychodynamics of the process of perception and awareness are intimately bound up with those of sleep. Fenichel (1945) has pointed out that the primitive modes of perception employed by psychotics, with their relatively vague and poorly differentiated experience of environment-reality, are identical with those of infants. There is a poverty of sharp distinction both between perceived objects and between the relationship of the sensory experience and the experiencing self. But such awareness patterns, poorly knit and without their normal relationship to such interpreting and normally acting mechanisms as the faculty of associative recall, are also typical of the diminished intensity of consciousness in sleep. It is with the essential identity of these three patterns of awareness—in infancy, in schizophreniform states, and in sleep—that we finally concern ourselves here.

Conclusions: Sleep and the Problem of Anoxia and Awareness

Hughlings Jackson has observed, "Find out all about dreams and you will have found out all about insanity." It is comparatively recently that physiologists have begun to interpret the findings of dynamic psychology in their schema. Yet, intimately associated as sleep is with awareness, it is impossible to neglect the interrelationships of such concepts with the somatic functional disturbances associated with these states.

We have shown (Lovett Doust, 1951a) how conscious awareness is a fluctuating variable, ever in this condition, and with extremes of the complete lack of awareness of deep coma states on the one hand and, on the other, those states

of heightened awareness in normal individuals which we have designated by the term "attention peaks." And accompanying such variations in the pattern and continuum of awareness, with its subjectively experienced panorama of consciousness, we have shown a like picture of oximetric variation. An attention peak in consciousness is accompanied by an oxamic peak in the arterial blood oxygen saturation levels; a state of reverie or inattention is accompanied, in temporal identity, by anoxaemia. A correlate of awareness variation is oxamic variation; the appearance of the one postulates the appearance of the other, and vice versa; the one would seem the mirror image of the other—two different ways of viewing a single phenomenon and its ever-changing patterns. It is as easy to follow the progressive diminution in awareness to the levels of sleep, or the intense and overwhelming desire for it accompanying periods of forced wakefulness, or the incarceration of a subject in a low oxygen-pressure chamber equipped with a mechanism allowing for a progressive increase in the simulated altitude to 12,000 ft. (3,658 m.), as it is to follow the progressive anoxaemia occurring in natural sleep as awareness is gradually shut off, in step-like fashion as has been shown, down to the deepest levels of plane 4, and the dramatic anoxia represented by an arterial oxygen saturation level of 87%.

A final point must now be considered. Time and time again it was noticed (Figs. 1, 2, and 4) that the sleeper woke with his blood oxygen saturation levels still low. They climbed back only slowly to their former base-line values. The sleeper was awakening; although no longer asleep he was, however, far from completely conscious. The slurred speech, confused ideation, the weary passage of his hand across his brow, and the frequent yawning were all important evidence of a diminished state of awareness. It would not seem legitimate, therefore, to correlate the diminished oxygen levels completely with sleep, but rather to identify them with the levels of relative unawareness which are so much the necessary components of sleep.

And just as dreams subjectively portray the enrichment of the fantasy life of sleep, so this same enriched fantasy and these same dreams are seen in the phenomenology of anoxia, infancy, and schizophrenia. The qualities of the "real" change their values in anoxia and in dreams—that is, in these states of altered consciousness the schizophrenic-like mutisms, perseverations, autisms, and illusion-delusions merge with hallucinations of every modality of sensation; the dream world is one of bizarre yet essentially personal and meaningful reality, but on a plane and in a sequence ill understood enough by the dreamer—and how much less by the observer.

To be awake under such conditions and in such a nightmare is, in a word, to be a schizophrenic—Jung's "a dreamer in a world, awake"—but to be asleep is the experience of us all. And when the homeostatic realignments which serve, perhaps, the purposes of sleep are accomplished we are recalled to the state of conscious awareness once again.

The oxygen saturation levels of the constitutional schizophrenic, as determined oximetrically (Lovett Doust, 1952), are those of the dreamer. When the attention peaks which have maintained him by conscious empathic effort give, he sinks back into a state of "wakened dreams." His levels of awareness are those of unawareness of all modalities save those of his unconscious; his oxygen saturation is that of the sleeper, and fluctuates uneasily as the sleeper, dreaming, twists and turns, mutters and sighs, groans, and snores his way through sleep.

Summary

The sleeping habits and levels of sleep of seven normal healthy subjects were studied.

Photoelectric oximetry in a series of 22 observations suggested seven planes of sleep. These planes were: (1) wakefulness (arterial oxygen saturation 96%); (2)

pre-sleep (90–92%); (3) light sleep (89–91%); (4) deep sleep (87–88%); (5) light sleep following deep sleep (89–91%); (6) pre-wakefulness (90–92%); (7) awakening (92–98%).

Muscular movements, posture, scratching, respiratory adjustments, and responses to external stimuli were found to correlate differentially with all these separate planes.

It was seen that the various physiological concomitants of sleep closely resembled those accompanying states of anoxaemia.

The theories of sleep are reviewed, and it is suggested that the concepts of homeostasis and dynamic psychology, psychiatry, and maturation bear an important relationship to the phenomena of fluctuating awareness, anoxia, and sleep.

It is a pleasure to express our gratitude to Professor Harold G. Wolff and Dr. Stewart Wolf for their constant encouragement and for the provision of facilities enabling this work to be carried out.

More medical students should be admitted to Oxford University, according to the report for the year ending July 31, 1951, of the Regius Professor of Medicine (*Oxford University Gazette*, February 9, p. 499). At present 55 men and 10 women are admitted to preclinical studies each year, and divided among the 30 colleges, which makes teaching arrangements very difficult. The restriction to 32 clinical students annually is satisfactory, however, since many of these students come from other universities, while Oxford students are encouraged to pass on to London.

SYMPTOMATOLOGY OF CONGESTIVE AND SIMPLE GLAUCOMA

A STUDY IN CONTRAST

BY

S. J. H. MILLER, F.R.C.S.

Assistant Ophthalmic Surgeon, St. George's Hospital,
London(From the Glaucoma Clinic, Institute of Ophthalmology,
London, W.C.1)

The cardinal feature of glaucoma is a raised intraocular pressure, as was first fully established by the Scottish physician, William MacKenzie, in 1830. He ascribed the raised tension to an increase in the watery contents of the globe due to a serous choroiditis. Sometimes increased tension is associated with, and secondary to, a concomitant pathological process, but the cause of the increased pressure in primary glaucoma is neither obvious nor well understood. Raised intraocular pressure in itself is, of course, not recognized by the patient, but it is associated with a variety of symptoms.

In the adult there are two main types of primary glaucoma—congestive and simple—and they differ clinically in their mode of onset. The former is characterized by symptoms of haloes and blurred vision or by an acute congestive attack; the latter by an insidious onset which usually escapes notice until the disease is well established. Congestive glaucoma is so often accompanied by a shallow anterior chamber with a narrow chamber angle that the disease is frequently designated, in American literature, as "primary narrow chamber angle glaucoma" (Friedenwald, 1949).

Simple glaucoma is associated with any breadth of chamber angle. Analysis of the series of cases examined gonioscopically at the Institute of Ophthalmology (Hobbs, 1950) in the main supports this generalization, as shown in Table I.

TABLE I.—Angle of the Anterior Chamber in Glaucoma

	Narrow	Medium	Broad	Unclassified
Congestive	61	12	2	6
Simple	20	43	32	4

Angles which were completely obstructed by peripheral anterior synchia were unclassified.

Early Signs: Congestive Glaucoma

The most dramatic form of onset is the acute attack of congestive glaucoma which usually starts in the hours of darkness and is characterized by severe pain in the eye irradiating throughout the distribution of the trigeminal nerve. There is profuse lacrimation, the eyelids and conjunctiva may be swollen, the eye itself red, angry, and hard, with a dull insensitive oedematous cornea and a dilated pupil. Vision may be reduced to perception of light, and severe prostration is often accompanied by nausea and vomiting. Such an onset may occur without warning and with great suddenness in an eye which is apparently healthy. On the other hand, the attack may be preceded by prodromal symptoms. In a small series of 20 cases of acute glaucoma for which a broad iridectomy had been performed in one eye, eight cases had prodromal attacks and 12 had no warning symptoms.

Warning symptoms, when they occur, are therefore of some importance, because their recognition may avoid the onset of an acute congestive attack. They consist of haloes or rainbows round lights, short-lived attacks of pain in the

eye, and temporary blurring of vision. Such symptoms are always evanescent and periodic, and their significance may not be realized by the patient or sometimes by the physician.

A glaucomatous halo is best seen on looking at a point focus of bright light in a dark room. Two coloured rings are usually seen, an inner blue-violet and an outer yellow-red. They are produced by the diffraction by tiny droplets of fluid in an oedematous cornea of the rays of light emitted from the point source, their physical causation being analogous to that of the naturally occurring rainbow. There are other causes of haloes, chief among which is senile sclerosis of the lens. Glaucomatous haloes are always temporary, however, whereas lenticular haloes can be demonstrated at any time of day under suitable conditions; furthermore, when glaucomatous haloes are viewed through a slit they suffer a diminution in intensity, whereas lenticular haloes appear to be broken up into sectors.

Haloes occurring early in the course of the disease may be said to be pathognomonic of congestive glaucoma. Of the 81 cases of congestive glaucoma detailed in this paper 73 were aware of haloes, although not necessarily as a first symptom, and eight had an acute attack without prodromal symptoms. Haloes also occur late in the course of simple glaucoma, and of the 99 cases of simple glaucoma examined 11 advanced cases gave a history of coloured rings round lights. That they are not entirely a function of a narrow chamber angle is shown in Table II.

TABLE II.—Incidence of Haloes in Both Congestive and Simple Glaucoma and the Nature of the Chamber Angle

	Angle	Haloes	Absence of Haloes
Narrow		59	22
Medium		13	42
Broad		5	29
Unclassified		7	3

It is often maintained that haloes are easily overlooked by a poor witness or that other subjective visual disturbances may be misinterpreted as haloes. On the other hand, if the patient is reasonably intelligent and the examiner careful to elicit a detailed description, including the presence of colour, there is little possibility of confusion. In this series of cases examined at the Institute there are examples of patients with lenticular haloes who have been using daily miotics unnecessarily, and there are others who have lost the sight of one eye, a tragedy which could have been avoided had the patient realized the significance of haloes seen round lights, a few years earlier. As Duke-Elder (1940) has written, haloes are regarded by some patients "with interested amusement and by others with lively terror." Prognosis is much better in the latter group.

Simple Glaucoma

Simple glaucoma has a different type of onset of a very insidious nature. The presenting symptoms are not specific and may have a varied pathology. Sometimes there are no ocular symptoms at all in the early stage of the disease, and it is first suspected on routine ophthalmological examination. An early symptom is difficulty in close work. Patients ascribe their troubles to a haze on their spectacle lens unrelieved by frequent cleaning. They find it difficult to describe their symptoms in detail; the print is out of focus, grey in colour when viewed through the affected eye, and uncertain in outline. Patients who present these symptoms may be short- or long-sighted, and their difficulty is due to a reduction in their power of accommodation.

It has been observed in the glaucoma clinic that a patient who reads 6/5 and J2 with his glasses when the intraocular pressure is within normal limits may require an addition of +0.5 D sphere to his distance glasses and an addition of as much as +2.5 D sphere to his reading glasses to attain the same visual acuity when his intraocular tension is raised. The commonest presenting symptom is a permanent blur

FIG. 1.—Case 305 (glaucoma simplex). Chart of intraocular tension. — Right eye (glaucoma simplex). ---- Left eye (normal).

in the vision of one eye. This is not a sign which occurs early in the course of the disease, for examination of such a patient will show a well-marked defect in the visual field which must have developed over a considerable period of time. The loss of field, however, is insidious, and at first monocular, so that it remains unnoticed until such time as the normal eye is occluded—usually by accident. There are two other later signs—constant eye-ache and a noticeable gap in the field of vision. These are, however, late symptoms which force themselves into the consciousness of the patient only after considerable ocular damage has been done.

The earliest symptoms noted in simple glaucoma cannot be explained entirely in terms of intraocular tension. Difficulty in reading is probably due to the effect of a raised intraocular pressure on the ciliary muscle, so that the range of accommodation is decreased and the near-point recedes beyond the usual comfortable distance of 10 to 12 in. (25

to 30 cm.). Eye-ache can also be equated with intraocular tension, as in the patient whose 24-hour tension curve is shown in Fig. 1. The tension of the right eye lies wholly above 45 mm. Hg Schiøtz. Patients who complain of a gap in the field of vision have in fact a large scotoma which has broken out to the periphery so that a whole quadrant of the field is blank (Fig. 2), or they may show a relatively small scotoma which approaches close to the fixation point (Fig. 3). The latter patient was an amateur bee-keeper, and he noticed as a first symptom that bees walking across his right hand tended to disappear. Those who complain of a permanent blur in one eye have, as a rule, a combination of a definite field defect and an intraocular tension which is above normal limits during most or all of the 24 hours.

FIG. 3.—Case 207 (glaucoma simplex). Right field of vision charted May 4, 1951, by Mr. H. E. Hobbs. Blind spot mapped by 10-mm. white object at 2,000 mm. — 5-mm. white object. ---- 2-mm. white object. R.V.=6/6.

Table III analyses the first symptom noted by the patient in 180 cases of glaucoma examined at the Institute of Ophthalmology, London.

TABLE III.—Initial Symptomatology—First Symptom

	Congestive Cases	Simple Cases

Haloes	49	0
Constant eye-ache	0	13
Difficulty in reading	0	20
Gap in the visual field	0	13
Permanent blur in one eye	0	44
No symptoms	0	9
Total	81	99

Variations in Intraocular Tension

Congestive Glaucoma

The reason for the evanescent nature of the symptoms of congestive glaucoma is found in the behaviour of the intraocular pressure in an untreated case. Fig. 4 shows that the tension is highest just before going to bed, when the symptoms of haloes, blurring, and pain are at their height, and lowest in the morning after sleep.

That sleep has a beneficial effect on the symptoms of congestive glaucoma is well recognized by patients. Their eyes are usually easier in the morning, and even a doze in the middle of the day will relieve them of blurring or ocular

FIG. 2.—Case 16 (glaucoma simplex). Left field of vision charted March 27, 1949. 3-mm. object at 330 mm. distance. L.V. = 6/6.

FIG. 4.—Case 291 (congestive glaucoma). Chart of intraocular tension.

pain. Fig. 5 shows the effect of sleep in an untreated case. Emotional strain and fatigue have a contrary effect and precipitate rises in tension.

An important aspect of these observations lies in the recognition of the episodic nature of the increased intraocular tension in congestive glaucoma. Early in the disease haloes may be noticed only occasionally—perhaps once a fortnight—so that whole days or weeks may pass without a rise in intraocular tension. As the disease progresses, haloes become more frequent, but a patient who gives a history of nocturnal haloes may have a normal tension when examined at a morning clinic. The only clue to the diagnosis is often a history of haloes, and confirmation of their glaucomatous nature in terms of Schiötz tonometric readings requires an examination of the patient *when the symptoms are in evidence*.

FIG. 5.—Case 281 (congestive glaucoma). Chart of intraocular tension.

Simple Glaucoma

The variations in the intraocular pressure of simple glaucoma which have been investigated and described by Langley and Swanljung (1951) differ from those of congestive glaucoma in one very important aspect. The diurnal variation tends to be constant in extent and time, so that any 24-hour period is diagnostically as suitable for examination as another. It is true that early in the disease the intraocular tension is within normal limits at most times in

the day, so that a single Schiötz reading is of very little value. The diagnostic importance of a 24-hour tension curve in doubtful cases has probably been underestimated, and this is best undertaken in both types of glaucoma *before miotics are prescribed*. The variation in the intraocular tension in a normal eye during 24 hours is in the region of 3 to 5 mm. Hg Schiötz, with an upper limit of 25 to 27 mm. (Fig. 6). Most glaucoma curves are abnormal in two respects—the range of the variation and the maximum height of the curve.

FIG. 6.—Case 185 (no evidence of glaucoma). Chart of intraocular tension.

The difference in the two groups is emphasized in Table IV, which shows that a high percentage of patients with simple glaucoma are unaware of a close association between their symptoms and the time of day; whereas most congestive cases find that their symptoms are consistently aggravated at night.

	Symptoms Worse		No Difference	Total
	Morning	Evening		
Congestive ..	5	62	14	81
Simple ..	8	19	72	99

Cupping of the Optic Disk

In Table III there was a small group of cases of simple glaucoma diagnosed on routine examination. These patients had no ocular complaints even in retrospect and, until the diagnosis was made, believed their eyes to be perfectly healthy. The clinical sign which raised the suspicion of glaucoma in the examiner's mind was cupping of the optic disk on one or both sides.

There are various forms of cupping of the optic disk, which can be differentiated from the glaucomatous type only with difficulty. A physiological cup may be deep, but it rarely involves the whole area of the disk, so that one side shows a gentle slope to the point of emergence of the central vessels. The excavated portion may be white and the mottled lamina cribrosa clearly discerned in its depths, but the remainder of the disk is usually pink.

A well-established glaucomatous cup involves the entire circumference of the disk with steep sides. It is white, sometimes with a peripapillary halo of the same colour where the sclera shines through an atrophied retina and choroid. All grades of cupping exist between the physiological and the pathological, and indeed the former may pass imperceptibly into the latter, so that at some stages of glaucoma their differentiation may be quite impossible. Of the 29 cases of doubtful glaucoma referred to the Insti-

tute for investigation, 27 had cupped disks. Follow-up investigation of this series of cases over some years will prove of great interest, for it is possible that some, at least, are in the preclinical stage of glaucoma simplex and will eventually disclose their true nature in response to one of the many periodic tests performed upon them.

Cupping of the optic disk is not an early sign of congestive glaucoma. Table V shows that 54 of 60 early cases of congestive glaucoma presented no pathological cupping, whereas all 88 early cases of simple glaucoma had some form of cupping, 83 of which were frankly pathological.

TABLE V.—Cupping of the Disk in Relation to Type of Glaucoma

	Pathological Cupping	Physiological Cupping	No Cupping
Congestive { early ..	6	9	45
{ late ..	19		2
Simple { early ..	83	5	
{ late ..	10	1	

There is a close association between cupping and field loss as shown in Table VI. Field changes may coexist, however, with a normal disk, or a normal field may be found in association with a clinically pathological cup. Both are probably the product of one process acting at a different locus and apparently independently.

TABLE VI.—Cupping of Disk in Relation to Visual Fields

	Fields		
	Full	Scotoma	Depressed
Pathological cupping ..	5	103	10
Physiological cupping ..	8	4	3
No cupping ..	34	4	9

Field Changes

Changes in the visual field are not an early feature of congestive glaucoma. The majority, as shown in Table VII, have no demonstrable field defect when the diagnosis is made, either centrally or peripherally. The late cases of congestive glaucoma have visual field changes in every way comparable to those found in glaucoma simplex, provided there has been no acute congestive attack.

TABLE VII.—Scotomata in Congestive Glaucoma

	Baring of the Blind Spot	Scotoma	Full
Congestive { early ..	15	2	43
{ late ..	8	13	

Of the 13 cases which had suffered an acute congestive attack, five responded to medical treatment. Four of these five had full fields and excellent vision, and in the other the field was markedly depressed, although vision was 6/6. Of the eight cases which had been treated surgically, two had cataracts, two had full fields, three had slightly depressed fields with good vision, and one had very depressed fields and poor visual acuity. Scotomata seem to be uncommon as a sequel to an acute congestive attack.

Perimetric findings are most valuable in the diagnosis of early glaucoma simplex. Their configuration was fully described by Traquair in 1935, and nothing new has been added since that time. The earliest sign is found by examining the patient with a large Bjerrum screen at 2 metres distance with a small white object 1 mm. or 2 mm. in diameter. Normally this isopter forms a circle subtending an angle of 30 degrees from the fixation point, so that the blind spot lies within its confines. In glaucoma simplex this isopter is altered in such a way as to lay bare the blind

FIG. 7.—Case 136 (glaucoma simplex). Left field of vision taken at 2,000 mm. distance on February 21, 1950. — 5-mm. white object. ---- 2-mm. white object. L.V. = 6/6

spot, which now lies outside the deformed circle. Small isolated scotomata then appear (Blaxter, 1950) which coalesce with the blind spot to form arcuate scotomata which spread above or below the fixation point (Figs. 7 and 8). Such signs are inconstant, and in untrained hands are difficult to elicit. All the cases of glaucoma simplex in this series had defective fields, the changes varying from baring of the blind spot to absolute amaurosis.

The Threat to Vision.—It follows as a corollary to the analysis of visual-field changes in the two groups of glaucoma that the threat to vision is much greater in the simple than in the congestive type. Congestive glaucoma being a disease of symptoms, ample warning is usually given of disturbed function. If adequate therapeutic steps are taken the danger to sight is not great, whereas simple glaucoma develops slowly and quietly with few symptoms and no apparent disturbance in function. In this series,

FIG. 8.—Case 310 (glaucoma simplex). Right field of vision taken at 2,000 mm. distance on June 5, 1951, by Mr. P. L. Blaxter. — 5-mm. white object. ---- 2-mm. white object. R.V. = 6/9.

cases with a visual acuity of less than 6/60 in one eye amount to 37% of simple and 11% of congestive cases. Only three of the congestive cases had an acute attack. The cause of loss of vision in the others was due to neglect of warning symptoms.

Incidence

Table VIII shows that the average age of diagnosis of simple glaucoma is later than that of congestive glaucoma and that the congestive type is more common in women. A positive family history was obtained in 10% of both types of glaucoma in the series examined. This figure cannot be accurate, for many patients have little knowledge of their close relatives.

TABLE VIII.—General Incidence

	Congestive	Simple
Average age of diagnosis ..	54.2 years	59 years
Sex ..	51 F.; 30 M.	47 F.; 52 M.
Family history ..	8/81	10/99

The relationship of glaucoma to refraction is drawn up in Table IX. The distribution curves in percentages (Fig. 9) are remarkably similar, showing two peaks at +1 D and at -1 D. Although the curve for simple glaucoma lies on the myopic side of that for congestive glaucoma, the disease is much less common in myopia than in hypermetropia.

FIG. 9.—Glaucoma and refractive error. — Congestive glaucoma. ---- Simple glaucoma.

TABLE IX.—Glaucoma and Refractive Errors

	Hypermetropic	Myopic	Emmetropic
Congestive:			
Up to 1 D ..	22	9	5
" " 2 D ..	21	1

" " >3 D ..	10	2	
Simple:			
Up to 1 D ..	26	17	12
" " 2 D ..	15	4	
" " 3 D ..	9	5	
" " >3 D ..	7	4	

Each patient was interviewed by a lady almoner, and a social history was obtained which included questions on occupation, home conditions, working conditions, financial state, and personality reaction. Table X indicates that many of them are anxious and nervous individuals, more especially among the congestive cases. On the whole, glaucoma patients are industrious and conscientious citizens who set high standards for themselves and who are easily disturbed if these standards are not met.

Typically, a patient with congestive glaucoma is an anxious and conscientious woman in the early fifties who

TABLE X.—Psychological Background in Glaucoma

Aggressive ..	3	3
No obvious pattern ..	17	47

complains of haloes and attacks of blurred vision, especially in the evenings, and on examination is found to be a hypermetrope with good visual acuity, full fields, and normal fundi, and whose eyes present shallow anterior chambers with narrow angles.

A patient with simple glaucoma may be a male or a female in the late fifties who has noticed a vague but constant difficulty in close work for some months and thought a change of glasses was necessary. Examination reveals a low hypermetrope or myope with poor visual acuity in one eye, scotomatous fields of vision, and cupped disk or disks; anterior chambers are of moderate depth and the angle is of medium breadth.

Sample analyses of the 75,000 or so persons registered as blind in Great Britain reveal glaucoma as the cause in 15% (Sorsby, 1951). Earlier diagnosis is one way by which this figure can be reduced. Research on the fundamental disturbance in glaucoma also depends upon the examination of early untreated cases before dysfunction gives way to organic change. The family medical practitioner is most likely to see the patient early in the course of the disease. He should suspect its presence in all patients over the age of 40 who request advice on their eyes, especially if they have ever seen haloes or if one eye is more affected than the other. If he were to refer such patients to colleagues competent to diagnose ocular disease, it is possible that cases of congestive and simple glaucoma would be diagnosed earlier and treated more effectively.

Summary

Analysis of 180 case histories of patients with glaucoma supports the following conclusions:

- (1) Congestive narrow-angle glaucoma has an acute onset or begins with periodic attacks of haloes, ocular pain, or blurring. Simple glaucoma has an insidious onset with unspecific ocular symptoms—reading difficulty, eye-ache, blur in one eye—or the disease may be diagnosed before symptoms arise.
- (2) Elevation of intraocular tension in congestive glaucoma is episodic, precipitated by emotional strain and fatigue, and relieved by sleep. The diurnal variation in intraocular pressure in simple glaucoma tends to be constant for any 24-hour period.
- (3) Cupping of the optic disk is not characteristic of early congestive glaucoma, but is nearly always found in simple glaucoma, and its extent is closely related to the degree of field loss.
- (4) Changes in the visual fields are not found in early cases of congestive glaucoma either centrally or peripherally. Central field changes are, however, an early and valuable sign of the simple type.
- (5) The threat to vision is less in congestive than in simple glaucoma.
- (6) Congestive glaucoma is diagnosed at an earlier age than is simple glaucoma and is commoner in the female sex. A genetic basis is found in 10% of cases of both types.
- (7) The distribution of the two types of glaucoma over the refraction range is very similar.

(8) Patients with congestive glaucoma are usually nervous and worrying individuals. This tendency is less marked in simple glaucoma.

(9) A plea is made that practitioners should suspect the disease in all patients over 40 years with eye symptoms, especially if haloes have been seen or if there is a unilateral disturbance of vision.

This analysis touches very briefly upon the work of Mr. G. D. Elphick on visual fields, Mr. H. E. Hobbs on gonioscopy, and Mr. D. A. Langley on the phasic variations in simple glaucoma, carried out at the Glaucoma Clinic under the direction of Sir Stewart Duke-Elder. The social histories were taken by Misses Abbey, Armstrong, and Collis; patients were mainly referred from the surgeons of Moorfields, Westminster, and Central Eye Hospital; the secretarial work was undertaken by Miss J. Brown: to all of whom my thanks are due.

CEPHALIC TETANUS WITH REPORT OF A CASE

BY

L. BAGRATUNI, B.M., B.Ch.

Registrar, Department of Clinical Biochemistry, Radcliffe Infirmary, Oxford

Cephalic tetanus is a rare disease developing after injuries to the scalp, face, or neck, and associated with palsies of cranial nerves III, IV, VI, VII, IX-X, XII, singly or in any combination. Although general tetanus does not always follow, the condition is invariably associated with some degree of trismus.

Cumstone (1918) and Raven (1940) both recognize a type of cephalic tetanus after head or face injury which is without palsy and in which trismus is the principal sign. This type should not strictly be included in the term "cephalic tetanus," since it does not differ from local tetanus as found in other parts of the body. For this reason it is suggested that the term "cephalic tetanus" should be limited to those cases in which there is a cranial-nerve palsy. For this reason, again, cases such as those of Hyman (1935), in which there was tetanus with trismus and slight neck stiffness after tonsillectomy, and Bagchi (1929), who reported generalized tetanus associated with discharging ears, are not true cases of cephalic tetanus, in spite of the injury being limited to the head.

Rose (1869) is generally credited with the first comprehensive description of the disease, although Sir Charles Bell reported a case in London in 1836 and Pollock another from Dublin in 1847. Brown (1912) reviewed 94 cases, and in 1935 Abel and Hampil comprehensively reviewed the earliest literature on tetanus in general. Jayme-Goyaz (1941) and Wetzel (1942) almost simultaneously published reviews on cephalic tetanus in relation to eye injuries. For the past 25 years the *Quarterly Cumulative Index Medicus* has reported on an average two to three cases annually, bringing the present reported total to over 200.

Case Report

A 19-year-old engineer's apprentice, was admitted to the Radcliffe Infirmary on July 17, 1949, as an emergency. His complaint was stiffness of the jaws for the previous 12 hours. There was nothing relevant in his past or family history, and he had always enjoyed good health. On July 7 he had had an accident while riding a bicycle along a flint road which was strewn with hay. He fell off and received a cut over his left eyebrow from a pedal. At no time was he unconscious. With a friend he telephoned for a car, which brought them to his doctor in five minutes. After cleansing, two stitches were put into the wound and he received a prophylactic injection of antitetanic serum into his left deltoid. He was home, in bed, within half an hour of the accident. On the next day he felt quite well except for a slight headache behind the left eye which lasted for two days. His doctor, however, advised him to remain in bed.

On July 16 he was allowed up by his doctor for the first time. He felt a little tired but had no other symptoms. Later in the day he had slight difficulty in closing the left eye, but took little notice of this. During the night he was awakened twice by an involuntary closure of the jaws which caused him to bite his tongue. On waking the following morning he noticed that he could not move the left side of his face as well as his right if he spoke or smiled. The left side felt "stiff." Next he noticed that the jaw was "stiff" on the left side. These symptoms progressed. At 8 p.m. he was seen by his doctor, who found a complete left facial palsy, trismus, and no other signs. He sent him into hospital. There had been no difficulty in swallowing and no stiffness anywhere apart from the trismus.

On admission he looked healthy and felt perfectly well apart from the palsy and slight trismus. In fact, he treated the whole matter as a joke. His temperature was 97.8° F. (36.6° C.), pulse 60, and respirations 20.

Examination showed a moderately deep wound over the left eyebrow, 1½ in. (3.8 cm.) long, sprinkled with penicillin powder. It was clean and there were no signs of inflammation. Multiple superficial abrasions were present on both elbows, extensor aspects of both forearms, both palms, and the left knee. These were healing well. There was no stiffness of the neck, back, or abdomen. He had a well-marked upper and lower facial palsy on the left, but could with an effort give a short whistle now and then. He could not close the left eye, although the right closed normally. The left naso-labial fold was almost completely obliterated. There was also mild trismus. No further abnormalities of the cranial nerves were found; the fundi appeared normal, and tone, power, movement, and reflexes in the limbs and abdomen showed no abnormality. The plantar responses were flexor. There was no abdominal rigidity. The cardiovascular and respiratory systems were normal. The blood pressure was 110/80. Urine analysis revealed no abnormal constituents.

Progress and Investigations

He was at once put to bed and given 100,000 units of antitetanic serum intravenously and 100,000 units intramuscularly. He received phenobarbitone and sodium amytal and was given a high-calorie high-protein diet. A skull x-ray film showed no fracture or other lesion.

July 18.—The stitches were removed and a swab was taken from the wound, which appeared quite clean. *Clostridium tetani* was not cultured from the swab. The haemoglobin was 17.4 g.%. The white blood cells numbered 5,000, with a normal differential count. The blood sedimentation rate was 1 mm. in one hour (Westergren). The Wassermann and Kahn reactions were negative. He was well and was fairly active in spite of the sedation. The accompanying photograph was taken on this day.

July 19.—The trismus was increasing and he was having difficulty in taking solid foods.

Photograph showing wound and left facial palsy on July 18.

July 20.—The trismus was worse. He complained spontaneously of diplopia for distant objects. The mouth opened $\frac{3}{4}$ in. (1.9 cm.). There was minimal weakness of the left external rectus muscle on looking to the left. He was developing a right-sided ptosis. He complained of some stiffness of the left side of his neck. There was no abdominal rigidity.

July 21.—The ptosis was more pronounced. The diplopia persisted, but it was difficult to

analyse in spite of the images being side by side. There was very slight dilatation of the right pupil. He complained of some blurring of vision. He was unable to take solid food. The wound was quite clean.

July 22.—The ptosis was increasing and there was slight impairment of upward movement of the right eye and slight limitation of lateral movement of the left eye. There was no difficulty in swallowing.

July 23.—The diplopia persisted for distant objects and there was occasional difficulty in swallowing.

July 24.—His sleep was disturbed by involuntary tongue-biting. The trismus was very marked on the left side and the mouth hardly opened, so that fluids had to be taken from a feeder. Occasionally fluids passed into the trachea but not into the nose. The diplopia persisted, but there were no signs of general tetanus.

July 27.—He began to improve. The mouth opened wider and the tongue-biting at night had become much less frequent. The facial palsy and ptosis remained as before. Movements of the left eye were improved, but the right eye movements were still impaired.

July 28.—The diplopia was improving.

July 31.—The ptosis was less marked and the mouth opened wider. He was taking solid food.

August 4.—The facial palsy remained unchanged. The mouth opened wider but fluids still entered the trachea at times although there was no difficulty in swallowing. Vision: right eye, 6/5 and Jaeger 1; left eye, 6/9 and Jaeger 1 with hesitation. The ptosis was improving, but the diplopia persisted. There were no pupillary abnormalities. Changes were observed in the left fundus for the first time.

August 9.—Seen by Mr. J. P. F. Lloyd at the Oxford Eye Hospital, with the following findings. Vision: right eye, 6/5; left eye, 6/18. Orthoptic report: cover test, near and distance slight convergence, rapid recovery; ocular movements show slight left external and left inferior rectus weakness; left superior rectus appears to overact. Synoptophore: angle + 3° straight ahead, + 5° laevoversion, and + 3° on dextroversion; fuses at + 3°; adducts 24°; abducts 4/5°. He still complained of horizontal diplopia on laevoversion and depression which was improving. The Hess chart was attempted, but the angle of deviation was too small. The fundi showed a lesion of the left macular, the fovea appearing to be situated in a small greyish area. This was thought to be due to macular exudate, detachment, or haemorrhage after the trauma of the accident. The 6/18 vision of the left eye was not improved by glasses. In Mr. Lloyd's opinion the incoordination of eye movement could not be attributed to any one muscle, but seemed to involve a midbrain nuclear disturbance.

August 10.—The patient was up and about in the ward. The ptosis was less marked and the mouth opened fairly well, but the facial weakness persisted. The wound was now well healed.

August 12.—Electromyography of the facial muscles showed normal nerve conduction on both sides on faradic stimulation. All facial muscles responded to both faradic and galvanic stimulation, although the response was slightly more sluggish on the left side. The electrical reactions were virtually normal. He was discharged home on August 13. During his 27 days in hospital his temperature rose to 100° F. (37.8° C.) on only four separate occasions.

When seen as an out-patient on September 6 there was some facial asymmetry at rest and upper and lower facial weakness was still present, but much less marked. The left palpebral fissure was slightly smaller than the right. The mouth still did not open fully, but he was eating and chewing his food normally.

On December 15, 1950, eighteen months after the initial injury, he was symptomless and quite well. At rest there was still minimal facial asymmetry, with the left nasolabial fold less marked than the right, but there was no facial weakness. The mouth opened fully, although he did not think it opened as well as before the injury. There were no eye symptoms or signs. Indeed, the only traces remaining of his illness were the well-healed scars over the eyebrow and slight facial asymmetry.

Discussion

In the days before serum was used Brown found the mortality in cephalic tetanus to be 53% in 94 cases, but in the 14 cases in which facial palsy preceded trismus this was raised to 64%. Wetzel's 30 cases after eye injury had a mortality of 80%. The six cases which recovered all had antitetanic serum. For general tetanus Cole (1940) found the mortality to be 38% in 43 consecutive cases in civilian practice. Pratt (1945) found a mortality of 43% among 56 children with all forms. Cole considered the prognosis bad for general tetanus if spasm appeared within 48 hours after injury and good if after this period. Reports certainly suggest that cephalic tetanus is more deadly than other forms and the prognosis is worse the earlier the signs appear.

The palsy may last a few days or persist for several months in the absence of other symptoms. The facial palsy is the most persistent, but recovery always seems to occur in the end. The present patient had a slight facial weakness two months after the initial injury. He was perfectly well apart from this. Sigwald's (1946) case, however, had a persistent facial palsy for seven months with no signs of recovery. This is very exceptional.

Ptosis also tends to persist, but usually for a shorter period. Palsies of the other cranial nerves are generally confined to the height of the illness only.

Pathogenesis and Pathology

The tetano-spasmin fraction of the tetanus toxin is fatal to man in a dose of 0.5 mg. Barnes and Trueta (1941) suggest that it is absorbed by the lymphatics and carried to the anterior horn cells by the blood. The work of Harvey (1939), Schaefer (1944), and Vincent and de Prat (1945), however, suggests that the spastic phenomena may be explained by a purely peripheral action of the toxin on the motor end-plate and proprioceptive endings, associated with increased liberation of acetylcholine.

The paralytic phenomena are very much harder to understand. Rose originally thought that the facial nerve swelled under the influence of the toxin and became strangulated in the stylo-mastoid canal, resulting in the commonest type of palsy. Watkins (1939) found an impaired sensation to taste associated with facial palsy and suggested a similar mechanism with involvement of the chorda tympani. Jayme-Goyaz quoted Mendel, who suggested that the third-nerve lesions were due to intense absorption of toxin from the orbicu-

laris and ciliary regions, which are supplied by this nerve. In Sigwald's case the limitation of ocular movement as determined by electrical tests was due to paralysis and not to spasm of the eye muscles. In the present case myograms of the facial muscles after the patient had improved showed little change from normal, although the response was more sluggish on the side of the palsy. Gunther and Walker (1943) found that in local tetanus myograms showed action currents present even at rest, with exaggerated summation during contraction and after a noise stimulus.

Baker (1943) reviewed the early literature on the pathological changes; it was extremely conflicting. It may be said in general that no definite nerve lesion had been found except for haemorrhages which might have been due to violent spasms. He recorded the case of a farmer who died of general tetanus after the removal of a wart from the hand. He died with irregular heart and respiratory action not associated with spasms and apparently due to failure of the respiratory and cardiovascular centres in the medulla. Sections of the brain showed destructive changes in the motor nuclei of the fifth nerve and in the dorsal nucleus of the tenth nerve. Minimal changes were found elsewhere, and there was no significant lesion of the anterior horn cells. Baker suggested that selective nuclear damage may often be a cause of death in tetanus, and is usually ascribed to respiratory spasms rather than paralysis. Such localized nuclear changes would certainly account for the bizarre ocular signs found in the present and other reported cases. Baker's patient had no ocular signs, and no damage was observed in any of the ocular nuclei. Reversible damage to the nucleus would account for the temporary nature of the paresis, and the extent of the damage would determine its duration.

Treatment

No matter how mild the initial symptoms may be, every case of cephalic tetanus should be treated as a potential case of general tetanus. Antitoxin should be given, 100,000 units intravenously and 100,000 intramuscularly, as soon as possible after the signs appear. Adequate sedation to prevent spasms, a special nurse, and a darkened room are essential. A high-protein high-calorie diet should also be given, by nasal tube if the trismus is intense.

Tongue-biting may be troublesome and the teeth may have to be wedged with gauze. The general nursing of the patient is often of greater importance than any specific therapy. Mephenesin ("myanesin") has been used to overcome the spasms and it is useful for feeding, but there is a danger of haemolysis (Torrens *et al.*, 1948).

Summary

Cephalic tetanus is defined as tetanus after head or face injury which is accompanied by some cranial-nerve palsy. A case with recovery is described.

The clinical picture involves bizarre palsies of cranial nerves III, IV, VI, VII, IX-X, XII, single or in any combination. Exceptionally, the chorda tympani may be involved. It is suggested that the condition results in transient or permanent damage to the cranial-nerve nuclei.

Prognosis is better than earlier reports suggest if prompt treatment with antitetanic serum and sedation is carried out.

I should like to thank Dr. A. M. Cooke for permission to publish this case and for helpful criticism in connexion with this paper. I should also like to thank Mr. J. P. F. Lloyd, of the Oxford Eye Hospital, for the eye examinations.

ESTIMATION OF TRYPSIN IN DUODENAL JUICE

BY

I. GORDON, M.B., M.R.C.P., M.R.C.P.Ed., D.C.H.

B. LEVIN, M.D., Ph.D., B.Sc.

AND

T. P. WHITEHEAD, A.R.I.C.

(From the Queen Elizabeth Hospital for Children, London)

It has been shown (Andersen, 1942) that trypsin is always low or absent from the duodenal juice in fibrocystic disease of the pancreas, and this forms a reliable basis of diagnosis. Andersen has pointed out that the estimation of proteolytic enzyme need not be exact, as there is a fairly wide difference between the amounts found in fibrocystic disease and those found in other conditions, and she therefore adopted a simple modification of Fermi's method (1906) for routine estimation of trypsin. For some time we have been using a modification of the method of d'Este Emery (quoted by Harrison, 1930), which utilizes the gelatin of an x-ray film as substrate for estimating trypsin in duodenal juice and faeces. It has the advantage of ease and simplicity and is accurate enough for diagnosis. A similar method has been described for faeces by Shwachman, Patterson, and Laguna (1949), who appear to have overlooked the prior description.

In this investigation, using the method of James (1951) for aspirating duodenal juice, the normal levels of trypsin have been determined by the x-ray film method; a comparison has been made between this method, the gelatin method of Andersen, and a more accurate method based upon the proteolytic action of trypsin on casein (Northrop, 1924).

Method of Intubation

An ordinary duodenal tube containing a magnet in the tip was used as in the method of James (1951). In an infant the 10 o'clock feed was not given; in the older child breakfast was omitted so that intubation was performed with the stomach empty. There was no restriction of fluids. Sedatives were unnecessary; in several instances where one was given a longer time was needed to obtain a satisfactory specimen of duodenal juice, possibly because of the diminished gastric peristalsis or because the patients were more restless when the tube was passed. Whenever possible the tube was passed through the nose, as better control was thus obtained. In most cases a small plotting compass— $\frac{1}{2}$ in. (1.25 cm.)—with a non-dipping needle was used to locate the tip. The point at which maximum oscillation of the needle occurred was found by experience to be always

$\frac{1}{4}$ in. (1.25 cm.) away from the tip as seen by a radiograph. The position of the tip of the tube could not be accurately defined when it lay directly below the rectus muscles unless its position was approached by a deep palpation, with the compass underneath the rectus muscle. In all cases, as soon as the tip was thought to be in the duodenum, its position was confirmed by a radiograph. Of the 48 cases investigated only 2 were unsuccessful at the first attempt, and when repeated no difficulty was encountered. The time taken for intubation varied from 20 minutes to two hours, the majority taking about one hour.

Whenever possible the duodenal juice was allowed to drip out without suction, but it was sometimes found desirable, especially when the fluid was viscous, to apply gentle suction with a syringe to reduce the time of collection. The juice was always collected in approximately 0.5-ml. amounts in separate tubes, thus avoiding the possibility of gastric juice contaminating the whole specimen. The most characteristic specimens of duodenal juice, as judged by colour, clearness, absence of mucus, and the pH, could then be pooled and used for analysis. Estimation of trypsin was performed as soon as possible after the duodenal juice had been obtained, being kept ice-cold in the meanwhile. If the analysis were performed the following day, the specimen was kept frozen. Under these conditions there seems to be no diminution in tryptic activity up to 48 hours.

Estimation of Trypsin

Gelatin Method

Andersen and Early's (1942) directions were followed, except that *U.S.P.* gelatin was used instead of Knox gelatin.

X-ray-film Method

Serial dilutions of duodenal juice from 1 in 2 to 1 in 4,096 are prepared by adding accurately 0.2 ml. of the fluid to the first of the series of 12 test-tubes—2 by $\frac{1}{4}$ in. (5 by 0.6 cm.)—each containing 0.2 ml. of 1% crystalline sodium carbonate solution. After mixing, exactly 0.2 ml. is removed and added to the second tube, and so on up to the sixth tube, from which 0.2 ml. of the mixture is discarded. To the seventh tube is added 0.2 ml. of duodenal juice already diluted 1 in 32 with 1% sodium carbonate solution, and serial dilution effected as before up to the twelfth tube. In this way the large errors which may occur in carrying out 12 successive serial dilutions were avoided.

With a Pasteur pipette, 1 drop (approximately 0.05 ml.) of undiluted duodenal juice is placed upon a 5-cm. square of unused x-ray film. Then a drop of each of the serial dilutions of the juice are separately placed thereon, starting with the weakest dilution, and finally 1 drop of 1% sodium carbonate solution as a control. The spots are numbered for convenience from 1 (undiluted juice) to 13. Care is taken in delivery that each drop occupies approximately the same area of film. The latter is then transferred to a covered Petri dish containing a moist pad of cotton-wool to prevent drying, and incubated at 37° C. for 30 minutes. The film is then placed in the freezing chamber of a refrigerator for 20 minutes. In all transfers care is taken that the drops are not displaced. Finally the film is washed in a stream of cold water from the tap. If sufficient trypsin is present in any of the drops, a clear circular translucent area is left after the drop is washed off. The control spot remains unaffected, apart from a slight roughening of the surface.

It is essential to place the film in the freezing chamber of the refrigerator before washing in tap water, since the gelatin of the film may be softened by any fluid at 37° C., and if not well cooled may be subsequently washed off in too strong a stream of cold water. The end-point is taken as the highest dilution of duodenal juice giving a completely translucent area. For simplicity the spot number may be reported instead of the dilution. Although used or unused film may be utilized, we have found it preferable to employ unused Kodak film. Other makes give slightly different

results. Duplicate estimations were always performed and there was no difficulty in getting good agreement between duplicates.

Casein Method

The method of Northrop (1924) was used. To approximately 17 ml. of distilled water is added 1 g. of soluble casein *B.P.* and the mixture is well shaken to dissolve. Then 6 ml. of 2% crystalline sodium carbonate solution is added, followed by 0.5 ml. of duodenal juice, and the solution made up to 25 ml. in a volumetric flask with distilled water. After inverting several times to mix, 1 ml. is at once removed as a blank, placed in a test-tube containing 2 ml. of water, and 2.5 ml. of 10% trichloroacetic acid solution is added. After standing for five minutes the precipitated protein is filtered off. The remainder in the volumetric flask is incubated at 37° C. for 45 minutes, after which 1 ml. is removed and treated as before. From both these filtrates 3 ml. is removed for the estimation of nitrogen by the micro-Kjeldahl method. From the difference between the two results the number of milligrams of non-protein nitrogen produced by the action of 1 ml. of duodenal juice on 4% casein solution under these conditions is calculated.

Material

Duodenal juice was obtained from 48 infants and children. The total included 15 normal children aged 3 weeks to 2 years; 8 with fibrocystic disease of the pancreas, aged 3 to 14 months; 20 with symptoms suggestive of coeliac disease or fibrocystic disease, aged 7 months to 2½ years; and 5 marasmic infants aged 14 months to 3 years. All specimens of juice except two were golden yellow due to bile, the two exceptions being light green. The specimens from cases of fibrocystic disease were thick viscous fluids, whereas all the others were thin and mainly clear. The pH ranged from 7 to 8.3, except for one which was pH 5.8, although this gave a normal level of trypsin.

Results

The results of the estimation of proteolytic enzyme by the x-ray-film method in the duodenal juice from 48 infants are shown in the Chart. In 7 of the 48 specimens no trypsin could be detected. One further case showed a very low amount of trypsin, giving an end-point in a dilution of 1 in 2 only (spot 2). All these were diagnosed as fibrocystic disease and treated as such. The remainder showed end-points at spots 6 to 11 inclusive, with the largest number at spot 7. There is a wide margin, therefore, between the cases of fibrocystic disease and the others, and this result is also obtained with Andersen's gelatin method as shown in the Table. There were no cases of coeliac disease, marasmus, or possible fibrocystic disease (other than proved cases) in which the amounts of proteolytic enzyme fell below the lowest level found in normal infants.

Chart showing trypsin levels of duodenal juice in 48 infants.

Comparison of X-ray-film Method, Andersen's Method, and Casein Method

In a preliminary experiment, using serial dilutions of pancreatin (*B.P.*) containing from 200 to 0.2 mg./ml., parallel results were obtained by all methods. The amount of trypsin in the duodenal juice from 14 infants was estimated by

Trypsin in Duodenal Juice of Infants. Comparison of the Three Methods

Specimen No.	X-ray-film Method Spot No.	Gelatin Method (Andersen) Tube No.	Casein Method mg./N/ml.
1	Nil	Nil	Nil
2	"	"	"
3	"	"	"
4	6	4	52
5	6	3	67
6	7	4	67
7	7	2	85
8	7	2	96
9	7	2	115
10	7	2	124
11	8	4	54
12	8	3	83
13	8	3	88
14	10	4	93

all three methods (see Table). Although the results given for the x-ray-film method and Andersen's gelatin method show a close relationship, they are not exactly parallel. Of the three cases of fibrocystic disease, two showed no trypsin by both methods, and the third gave the same low result. However, among the normals, specimens of duodenal juice which gave identical levels of trypsin by the x-ray-film method gave levels that differed by as much as three tubes by Andersen's method. These differences are to be expected, since neither method can be considered accurate as compared with the casein method. For example, duodenal juice with an end-point at spot 7 can give a range of 67 to 124 mg. of nitrogen by the casein method and an even wider range is obtained with specimens of duodenal juice giving an end-point at spot 8. A similar wide variation is shown with Andersen's method. Results are, however, generally parallel with all three methods.

The results obtained in this investigation show that the x-ray-film method is entirely adequate for the differentiation of fibrocystic disease from other conditions. It is especially suitable as a routine clinical laboratory procedure; it is simple to perform, less juice is required, and it is less time-consuming than other methods, since results can be obtained within an hour. The use of James's method of intubation in conjunction with the x-ray-film method of estimation of proteolytic enzyme makes the investigation of suspected cases of fibrocystic disease of the pancreas relatively easy.

Summary

The amounts of trypsin in the duodenal juice of 48 infants and children, including 8 suffering from fibrocystic disease of the pancreas, have been determined by a method utilizing the gelatin of x-ray film as substrate. This method, which has advantages of ease and simplicity, has been compared with the gelatin method of Andersen as well as with a more accurate casein method, and has been shown to be accurate enough for the diagnosis of fibrocystic disease of the pancreas.

We would like to thank Dr. A. H. James for originally demonstrating his method of duodenal intubation, and Dr. W. F. Young and Dr. A. H. James for obtaining some of the specimens of duodenal juice.

On the day of the total eclipse of the sun a million Hindu pilgrims bathed in the sacred lakes at Kurukshetra (East Punjab). *The Times* special correspondent (February 26) pays special tribute to the excellent public health arrangements. All pilgrims were inoculated compulsorily against cholera, all water (including the sacred lakes) chlorinated, and D.D.T. sprayed throughout the pilgrim camps, and no outbreak of disease has been reported.

ACUTE IDIOPATHIC PAROXYSMAL COLD HAEMOGLOBINURIA OF NON-SYPHILITIC TYPE IN A CHILD

BY

W. P. SWEETNAM, M.D., M.R.C.P., D.P.H., D.C.H.

Paediatrician

E. F. MURPHY, M.D., D.C.H.

Senior Paediatric Registrar

AND

R. C. WOODCOCK, M.B., B.Ch., D.C.P.

*Registrar in Pathology**Halifax General Hospital*

Haemoglobinuria, in contrast to haematuria, is a clinical sign which is so seldom seen in paediatric practice that its appearance is a matter of unusual interest and significance. In the great majority of cases there is either clinical or serological evidence of congenital or acquired syphilis, although in the last decade this disease has become increasingly rare.

The syndromes of paroxysmal cold haemoglobinuria associated with cold haemagglutination and paroxysmal cold haemoglobinuria as found in syphilitics were first clearly distinguished by Stats and Wasserman (1943). Cases of paroxysmal haemoglobinuria induced by exposure of the body to cold in which clinical and serological evidence of syphilis is lacking have been described by Stats and Wasserman (1943), Stats, Wasserman, and Rosenthal (1948), Malley and Hickey (1949), and Ferriman *et al.* (1951). These last observers, in an analysis of the reported cases, could find only 12 in which the aetiology is unknown. All were in the later age groups, only one (aged 38) being under 50.

Case Report

A boy aged 3½ was admitted to hospital with a history that on three days during the previous fortnight he had been out with his father (a general practitioner) on his rounds and, on returning home, complained of a headache and vague abdominal pain, had what appeared to be a rigor, and immediately afterwards passed dark urine "like burgundy." On each occasion very low environmental temperatures were present. His symptoms cleared completely in a matter of minutes and his urine became clear in about 12–18 hours. It had also been noticed that the child developed a dusky blue discoloration and puffiness of the hands and ears on exposure to cold, suggestive of Raynaud's phenomenon.

On admission the child was of normal size and weight, active, and of good nutrition. He was pale, with a slight icteric tinge. Neither liver nor spleen was palpable. His pulse was 70 and regular and the blood pressure 110/70. Pulsation of arteries in the upper and lower limbs was normal. There was no history of any previous illness. The family history was irrelevant.

Investigation of Urine.—During a paroxysm the urine was the colour of burgundy and of high specific gravity (1026–1030). Albumin was present. The benzidine test was positive and spectroscopy showed the presence of oxyhaemoglobin. No red cells were seen on microscopical examination. Immediately after an attack a trace of bilirubin was detected and urobilinogen was found in an increased amount. In the intervals between attacks spectroscopy did not show any oxyhaemoglobin and albumin was absent. Haemosiderin was present on two occasions only (Prussian-blue reaction).

Investigation of Blood.—During the period the child was under investigation the haemoglobin varied from 72% (10.7 g.%) to 82% (12.1 g.%) and the erythrocytes from 5.1 to 5.3 millions. Reticulocytes remained at 0.5%. The white cells varied from 8,000 to 13,000, with a normal differential count. The blood Wassermann reaction and Kahn test were repeatedly negative. The Donath-Landsteiner test was positive, serum haemolysins of the "cold" type being present to a titre of 1 in 4. An auto-agglutinin was present in the serum to a titre of 1 in 256 at 2–5° C. No agglutination occurred at 37° C. or at 20° C. (room temperature). When the tubes containing the "compatible" red cells which had been agglutinated by the patient's serum at 2–5° C. were warmed, complete and even dispersal of the cells occurred. No "incomplete" antibodies were detected, a direct Coombs test on the patient's red cells being negative. The acid haemolysis test (Ham, 1939) was negative. Oxyhaemoglobin and methaemalbumin (Schumm's test) were present in the serum during and shortly after an attack. The osmotic fragility of the red cells was normal.

Rosenbach Test.—While in hospital the child was encouraged to go outside lightly clad in the hope that a paroxysm might be induced; none occurred, probably owing to an improvement in the weather conditions. It was therefore decided to induce an attack artificially by a modified Rosenbach test in order to confirm the diagnosis.

Blood was taken from an arm; haemoglobin was not present in the serum, and urine passed at the same time contained no abnormal constituents. The same arm was immersed in water at about 5–10° C. for 10 minutes, no movement being allowed. Venous return was not obstructed. At the end of this period the arm was lifted from the bath. It was noted that the skin had become a mottled blue-and-white. Blood was immediately taken from the arm and a sample of urine obtained. The serum of this blood contained 380 mg. of haemoglobin per 100 ml.; methaemalbumin was present. The urine was of normal colour and contained haemosiderin, but no haemoglobin could be detected. The benzidine test was negative. Two hours later the blood serum still contained 250 mg. of haemoglobin per 100 ml. A specimen of urine obtained at this time was the colour of burgundy and contained haemoglobin and haemosiderin, the benzidine test being positive. No red blood cells were seen on microscopical examination.

Progress of Patient.—The child has been encouraged to lead a normal life and to go out in all weathers suitably clad—that is, wearing extra clothing, thick stockings, and gloves on exceptionally cold days. Eight months later no further attacks of haemoglobinuria had occurred, although occasional duskeness and puffiness of the hands in cold weather had been noticed. The child himself has not complained of any symptoms.

Discussion

In this country the only types of haemoglobinuria which need to be considered are (1) haemoglobinuria due to drugs, (2) march haemoglobinuria, (3) syphilitic haemoglobinuria, (4) paroxysmal nocturnal haemoglobinuria (the Marchiafava-Micheli syndrome), and (5) the idiopathic type.

The lack of any history of drug-taking or any preceding vigorous exercise clearly ruled out the question of drug or march haemoglobinuria. There was no past or present clinical or serological evidence of syphilis. The lack of persistent haemoglobinaemia and haemosiderinuria, the negative haemolysis test of Ham, together with the fact that the attacks occurred by day only, served to differentiate the condition from the Marchiafava-Micheli syndrome.

The diagnosis of haemoglobinuria due to cold agglutinins was finally confirmed by a provocative modified Rosenbach test and by the demonstration of autohaemagglutination at low temperatures and in high titre with complete reversal of the reaction upon increasing the temperature.

The child's paroxysms of haemoglobinuria, although dramatic and alarming events to the parents, appeared to cause little systemic upset. The degree of blood destruction

did not call for transfusion or even iron therapy. The adoption of common-sense precautions, such as the wearing of extra clothing on cold days, seems to have controlled the paroxysms without the necessity for curtailing the child's activities.

Summary

A case of idiopathic paroxysmal cold haemoglobinuria of the non-syphilitic type in a child aged 3½ is described. This is the youngest case yet reported.

The differential diagnosis of the types of haemoglobinuria met with in this country is discussed.

INTRA-ARTICULAR STREPTOMYCIN IN TUBERCULOSIS OF THE KNEE

BY

R. T. AHERN, M.B., D.P.H.

AND

G. P. ARDEN, M.B., F.R.C.S.

(From the Heatherwood Orthopaedic Hospital)

Until recently the accepted treatment of synovial-joint tuberculosis was prolonged immobilization of the joint, general sanatorium treatment, and ultimately, in many cases, some form of arthrodesis. This leaves much to be desired, as the treatment lasts for years, a disability is nearly always permanent, and in children there is serious disturbance of growth.

With the advent of streptomycin many have attempted to modify the above regime, but with only a limited success. Most of the papers published (Bickel *et al.*, 1948; Smith and I-Sen Yu, 1950) have been of cases treated by systemic streptomycin in late and well-established infections. The tubercle bacillus is only moderately sensitive to streptomycin, so to obtain the best effect it is essential to procure the maximum concentration of the drug at the site of the lesion. This should be done early before extensive fibrosis and cartilage damage obliterates the joint space, damages the joint, and reduces the blood supply to the affected areas.

Early Diagnosis

To obtain these optimum conditions we have attempted to diagnose cases early by gland and/or synovial biopsy, and we have given streptomycin by the intra-articular route (Stréeten, 1949).

By performing gland or synovial biopsies early in suspected cases a definite diagnosis can often be made (Arden and Scott, 1947). In the case of knee-, ankle-, wrist-, and elbow-joints a gland and/or synovial biopsy will give a positive result in 70–80% of cases. In the case of the hip- or shoulder-joint a synovial biopsy is hardly justified, but a gland biopsy can be readily carried out. We believe that all cases showing a chronic inflammatory process in a single large joint should be submitted to biopsy. Only by this method will it be possible to make an early diagnosis of a tuberculous infection of a joint.

It has been found necessary to give streptomycin intrathecally to cure cases of tuberculous meningitis. Streptomycin given locally into tuberculous sinuses has also been found to be most effective (Ahern, 1950). Jones (1948) has demonstrated that intra-articular penicillin can remain in a joint up to 48 hours after intra-articular injection, and that this was the best method of preventing joint infections in war wounds.

The Investigation

This report is an analysis of 10 cases of synovial tuberculous infection of the knee which have been treated by intra-articular streptomycin. Most of the cases had been treated previously, for varying periods, by rest and in a sanatorium, without much improvement. Only three cases were diagnosed early (within four months of the onset of symptoms).

The follow-up is fairly short (20.4 months) and the number of cases is small, but in a few the results have been promising enough to encourage further trial.

Since it is possible to cure 50% of cases of tuberculous meningitis, equal or better results should be possible in the case of joint infections.

In some cases difficulty was experienced in entering the joint cavity owing to fibrosis and partial obliteration of the joint space. During the period of treatment all joints were treated either by traction and immobilization or by immobilization in a plaster backslab. Later the joint was left free when the clinical appearance and sedimentation rate were normal.

In four cases streptomycin blood levels were estimated at six and twelve hours after the intra-articular injections (see Table). The level at six hours was about 100 μ g. per ml.,

Blood Levels of Streptomycin after Intra-articular Injection

Case No.	Intra-articular Dosage of Streptomycin	Blood Level (μ g./ml.)	
		6 Hrs. After Injection	12 Hrs. After Injection
1	1 g.	93	5.0
4	1 g.	106	8.0
5	1 g.	93	4.8
6	1 g.	106	3.5

but by twelve hours it had fallen to less than 10 μ g. It would appear to be unnecessary to give systemic streptomycin as well. Efforts to estimate the joint streptomycin level failed owing to there being insufficient joint fluid.

Case Reports

Case 1.—Boy aged 12. Pain and swelling of right knee first appeared in February, 1945. Had received prolonged conservative treatment, but condition reactivated on several occasions. Tuberculous focus in right upper zone of chest in 1947. Moderate synovial thickening of knee; 90° movement at start of treatment. No osseous focus and joint space normal on x-ray examination. Synovial membrane biopsy (May 25, 1949) positive for tuberculosis. *Treatment*: 21 bi-weekly intra-articular injections of 1 g. of streptomycin (August to November, 1949). Immobilization for three months in a Thomas splint. *Result* (21 months after treatment): Knee cool, no swelling; x-ray film as before; normal activities. *Comment*: Undoubtedly benefited from local streptomycin therapy.

Case 2.—Boy aged 6. Focus right hilum in 1947, and right talo-navicular joint in 1948. Recurrent effusions into right knee during 1948. Marked synovial thickening; warm; 10° movement at start of treatment. X-ray examination showed no osseous focus and normal joint space. Synovial membrane biopsy (April 13, 1950) positive for tuberculosis. *Treatment*: Four bi-weekly injections of 0.5 g. Child very uncooperative. Treatment stopped August, 1949. Traction for nine months in a Thomas splint. *Result* (24 months after treatment): Knee cool, no swelling; 10° movement;

1½ in. (3.8 cm.) lengthening; wearing calliper. X-ray appearances unaltered. *Comment*: Diagnosis proved eight months after a very short course of streptomycin. Re-activated 10 months after streptomycin therapy, with backward subluxation of tibia. Settled after further five months' conservative treatment.

Case 3.—Woman aged 28. Bilateral hilar foci and two spinal foci in 1947. Synovial swelling in right knee, with effusion, since May, 1949. At start of treatment movement not noted. X-ray examination showed no osseous focus and moderately reduced joint spaces. *Treatment*: Ten bi-weekly injections of 1 g. of streptomycin (August to September, 1949). Three months in plaster shell. *Result* (23 months after treatment): Knee cool, no swelling; movement 140°; normal activities. Final x-ray film showed no osseous focus and very much reduced joint space. *Comment*: Presumptive evidence of tuberculous infection very strong. Benefited from local streptomycin.

Case 4.—Girl aged 13. Pain and slight synovial swelling in right knee, July, 1949; one month in plaster cylinder. 5° movement at start of treatment. X-ray films showed no osseous focus and normal joint space. Bilateral healed hilar foci, August, 1949. *Treatment*: 10 bi-weekly injections of 1 g. of streptomycin (August to September, 1949). Nine months' traction in Thomas splint; nine months in walking calliper. *Result* (23 months after treatment): Knee cool, no swelling; movement 80°; calliper discarded after 11 months. X-ray film as before. *Comment*: Marked improvement following local streptomycin.

Case 5.—Man aged 29. Pain and swelling of right knee first appeared in April, 1949. Five weeks in plaster before admission in July, 1949. On admission knee cool; no swelling; movement 5°. X-ray film showed no osseous focus and normal joint space. *Treatment*: 22 bi-weekly injections of streptomycin 1 g. (August to November, 1949). Three months' traction in Thomas splint; six months in walking calliper. *Result* (21 months after treatment): Knee cool; no swelling; 25° movement. X-ray films showed a patchy decalcification of lower end of femur and upper end of tibia and normal joint space. *Comment*: An unusual patchy decalcification noted six weeks after start of streptomycin therapy—probably a streptomycin effect. Very slow to clear.

Case 6.—Man aged 21. Left-sided pleurisy in 1948. Pain, synovial swelling, and effusion in left knee first appeared in March, 1949. Tubercle bacilli not present in fluid on admission in July, 1949. Knee cool; slight swelling; 20° movement. X-ray films showed no osseous focus and normal joint space. *Treatment*: 22 bi-weekly injections of 1 g. streptomycin (August to November, 1949). Three months' traction in Thomas splint; seven weeks in walking calliper. *Result* (21 months after treatment): Recurrence of slight pain (May, 1951); slight swelling at inner side left knee. Final x-ray appearance: small localized osseous focus in upper inner border of tibia; good joint space. *Comment*: Had regained 90° movement by June, 1950. Slight synovial swelling had persisted since treatment. Mild reactivation with small osseous focus in May, 1951. Thirty degrees movement retained.

Case 7.—Woman aged 40. Tuberculous right hip in 1939; and tuberculous right kidney in 1949. Pain and swelling of right knee following a fall in October, 1948, about a year before admission. On admission slight synovial swelling; 30° movement. X-rays showed reduced joint space; very slight erosion of joint surfaces. *Treatment*: 12 thrice-weekly injections of 0.5 g. of streptomycin (February to March, 1950). Eleven months' traction in Thomas splint. *Result* (17 months after treatment): Knee cool, no swelling; 60° movement; 10° flexion contracture. Plaster cylinder applied on discharge in June, 1951. X-ray film showed no appreciable alteration. *Comment*: Quiescence not attained with local streptomycin. Synovial swelling and tenderness persisted. Settled subsequently after a further 15 months' conservative treatment and a course of systemic streptomycin.

Case 8.—Girl aged 3. Pain, synovial swelling, and effusion in left knee in July, 1949. Warm, tender, moderate swelling and effusion, and almost full movement, at start of treatment. X-rays showed no osseous focus and normal joint space. Biopsy showed inguinal glands, superficial and deep, to be positive for tuberculosis on December 9, 1949. Focus right hilum in July, 1949. *Treatment*: 12 thrice-weekly injections of 0.25 g. of streptomycin (December, 1949, to January, 1950). Two months' traction in Thomas splint. *Result* (19 months after treatment): Knee cool, no swelling; Full movement. X-ray film as before. *Comment*: An early case; proved infection overcome with local streptomycin therapy.

Case 9.—Boy aged 16. Pain and swelling of right knee in December, 1947; then treated conservatively for two years. At time of admission moderate synovial swelling; movement 20°. X-ray films showed coarse trabeculation, slightly reduced joint space, and irregularity of posterior part of femoral condyles. Biopsy showed inguinal gland (January 18, 1948) to be positive for tuberculosis. *Treatment*: 12 thrice-weekly injections of 1 g. of streptomycin (December, 1949, to January, 1950). Two months' immobilization in Thomas splint. *Result* (19 months after treatment): Moderate swelling persisted; 40° movement. January, 1951: Charnley's arthrodesis. X-ray film showed bony fusion. *Comment*: Local streptomycin failed, but moderately advanced erosion of joint surfaces was present at start of treatment.

Case 10.—Male, aged 44. Pain and synovial swelling right knee since March, 1949, x-ray film showing rarefaction. Pulmonary tuberculosis, March, 1949; positive sputum. *Treatment*: 12 thrice-weekly injections of 1 g. of streptomycin (April to May, 1950) plus 2 g. of P.A.S. intra-articularly thrice-weekly for same period. Eight months in walking calliper. *Result* (15 months after treatment): Pain and synovial swelling persisted. Charnley's arthrodesis, February, 1951. Synovial membrane at time of operation positive for tuberculosis. February 12, 1951, x-ray film showed bony fusion. *Comment*: Local streptomycin failed.

Discussion

The affected knee is indistinguishable from normal in Cases 1 and 8. Cases 3 and 4 are progressing well, have 140 and 80 degrees of movement and no pain, wear no support, and are back at work. Quiescence was attained in Case 5, but only 25 degrees of movement was regained. Quiescence was attained temporarily in Case 6, with 90 degrees of movement. Reactivation occurred 21 months later. Quiescence was not attained with local streptomycin in Cases 2, 7, 9, and 10. It is perhaps not without significance that treatment was discontinued after four injections in Case 2.

Reactions were few. One case developed a rash which did not interfere with treatment. A positive sputum in this case became negative on completion of treatment. A slight local reaction with increased temperature and tenderness not lasting more than 24 hours was occasionally noted, but this occurred only when difficulty was encountered in entering the joint and some of the streptomycin was injected into the soft tissues.

It will be at least two years before enough cases have been treated and followed for any final opinion on this method of treatment to be given. We feel justified in publishing this interim report in the hope that other surgeons seeing these cases early will try to establish a diagnosis and begin treatment before cartilaginous damage takes place.

The average case admitted to an orthopaedic hospital has had symptoms for a year or more.

Summary

The results obtained with intra-articular streptomycin in synovial tuberculosis of the knee are encouraging.

Early diagnosis by gland and/or synovial biopsy is essential.

Four of our ten cases have progressed well, and in two normal function has been re-established.

ANGIOMA VENOSUM RACEMOSUM WITH ANGIOMATOUS LESIONS OF SKIN AND OMENTUM

BY

IRVING GILBERT, M.D., M.R.C.P.

Consultant Physician, St. Andrew's Hospital, Billericay, Essex; Senior Registrar, Tilbury and Riverside Hospital

Vascular malformations and tumours of the central nervous system are sometimes associated with similar lesions of the skin and viscera. Such associations are known by the names of Sturge-Kalischer-Weber, von Hippel, and Lindau when the nervous tissue involved is either the cerebrum or cerebellum.

Wyburn-Mason (1943) quotes numerous instances of skin naevi coexisting with a variety of vascular lesions of the cord. However, he notes only seven instances in which angioma venosum racemosum is associated with a skin naevus, and quotes the cases of Cobb, Alexander, Rand, Sterling, and Jackinowicz, adding three cases of his own. In only one of these (his Case 12) was the skin lesion non-segmental. All cases described had the cord lesion in either the lower dorsal or the lumbar areas.

Subsequently, Cross (1947) published the first case of extensive subarachnoid blood vessels involving the whole of the cervical region associated with an angioma of the left side of the neck and prominent vascular markings of the upper part of the chest and over the seventh cervical vertebra. The present case appears to be the second one on record. Of additional interest is the occurrence of numerous small angiomas of the omentum and a further large skin naevus of the flank.

Description of the Case

The patient was a well-built boy aged 15. Three years before admission he jumped off a 5-ft. (1.5-m.) wall and landed on his feet. He sustained no obvious injury, but 30 seconds later, while walking, he developed occipital headache. He was laid up for two weeks at home, complaining of pain at the back of his head, across both shoulders, and radiating down the left arm as far as the elbow. He stated that for several weeks his left leg tended to drag, but that ultimately recovery was complete. He was well until 10 days before admission, when he made a racing dive, swam two lengths of the swimming-bath, and then suddenly developed pain across the forehead and at the back of the neck. He got out of the water and almost lost consciousness on account of the severity of the pain. He was taken home, where his headaches continued for two days, accompanied by vomiting.

Five days before admission, while lying in bed, the pain in the nape of his neck suddenly became worse and again

FIG. 1.—Large skin naevus over the left flank.

spread across the back of his shoulders. This lasted for three days. On admission he complained only of stiffness at the backs of both legs.

Examination showed him to be a tall, well-built boy. There was general weakness of the left upper limb only, while neck rigidity and Kernig's sign were both present. A large naevus was observed over his left flank and several small ones elsewhere (Figs. 1 and 2), including one within the distribution of the fifth cervical neuronal segment.

Lumbar puncture produced a xanthochromic fluid with raised protein and cells. Radiographs of the skull and neck were negative.

The patient improved gradually, and on discharge three weeks later had recovered completely and was symptom-free. In view of the history suggesting recurrent subarachnoid haemorrhage, the lumbar puncture findings, and the presence of skin naevi, a tentative diagnosis of angioma of the cervical spinal cord was made. Other systems were normal, blood pressure was not raised, and urine examination, E.S.R., and chest radiograph showed no gross abnormality. He was sent to a neurosurgical unit for further investigation, but while waiting for admission to this unit he had a recurrence of symptoms after a friendly tussle with a school friend, and was readmitted to hospital 10 weeks later. Symptoms consisted mainly of pain across the right shoulder which gradually spread down the right side of his body. Examination revealed gross weakness and hypotonus of the right arm and leg, with diminution of tendon-jerks on that side. Neck rigidity was marked, Kernig's sign was positive, whilst the right plantar response was extensor. No sensory loss was detected at this stage. Lumbar punc-

FIG. 2.—The left-flank naevus and other small naevi.

ture produced a clear fluid with evidence of spinal block.

There was a gradual increase of motor weakness, which spread to the left side of the body, so that five days after admission he presented a picture of quadriplegia. There was sensory loss to pin-prick up to the level of C5 and both plantar reflexes were extensor. Respiratory embarrassment developed, cough reflex was weak, and dysphagia was complained of. His general condition remained poor and gave great cause for anxiety, as it was obvious that the paralysis was gradually spreading.

A neurosurgical team was called in and laminectomy was performed. Unfortunately the patient did not survive the operation, and in view of the extent of the lesion it was doubtful whether it was amenable to surgical treatment. Post-mortem examination revealed a large venous angioma overlying the whole of the cervical cord (Fig. 3); numerous small angiomas of the omentum (Fig. 4); and the skin naevi previously mentioned, which of course were observed *ante mortem*.

FIG. 3.—Large venous angioma of cervical cord.

Discussion

Reference to the symptomatology of recorded cases (Wyburn-Mason, 1943) indicates a fairly constant pattern. There is sudden onset of pain of root type associated with subjective sensory phenomena of tingling and numbness. Weakness or paralysis supervenes sooner or later, and is followed by a variable degree of recovery. Relapse occurs, with general worsening of the clinical state. Although sudden stress of exercise may precipitate symptoms there is no real evidence that trauma plays a part in basic aetiology.

Wyburn-Mason suggests that vascular naevi of the skin are not associated with any special type of blood-vessel abnormality of the cord, but may coexist with any variety. Furthermore, such naevi may or may not occupy segmental skin areas corresponding to the state of the cord lesion.

However, it is worth noting the words of Stanley Cobb (1915), who says that skin naevi are at times of diagnostic value when segmental phenomena referable to the central nervous system are present, and that congenital vascular

FIG. 4.—Small angiomas of the omentum.

tumours arise from a developmental fault of the central nervous system, so these lesions may occur in any of the organs innervated by filaments from that neuromere. Appreciation of the skin naevi in this case enabled a correct pre-operative diagnosis to be made.

Summary

A case is described of angioma venosum racemosum of the cervical spinal cord associated with angiomata of the omentum and skin naevi of the same metameres. The diagnostic value of the cutaneous lesions is stressed.

I wish to thank Dr. Eliot Mackworth and Dr. Philip Buckley for permission to publish this case, and to express my appreciation of the efforts of Dr. L. Potaschmacher for his painstaking post-mortem examination.

Medical Memoranda

Two Cases of Tetanus Neonatorum Treated with Penicillin and Aureomycin

Umbilical tetanus is fortunately rare in the British Isles; possibly for this reason the literature on the subject is relatively scanty, and standard textbooks do not deal fully with the use of modern drugs in this condition. W. Sheldon, for instance, in his *Diseases of Infancy and Childhood* (5th edition, 1946, p. 24), recommends 20,000 units of antitetanic serum (A.T.S.) and sedation with chloral and magnesium sulphate. He does not mention the use of the sulphonamides or penicillin. The following cases may therefore be of interest. Both occurred before the end of the second week of life, and made a complete recovery.

CASE 1

An African boy aged 7 days had a history of constant crying. On examination some tendency to rigidity of limbs but no definite spasm was seen. The umbilical wound had not healed and was dirty and plastered with leaves. His temperature was 99° F. (37.2° C.) and pulse 130. Heart and chest were normal. He was given A.T.S., 100,000 units immediately, and penicillin "G," 200,000 units four-hourly, and the cord was dressed with sulphanilamide powder. By the afternoon of admission muscular spasm and trismus of the jaws was obvious. Sedation with chloral hydrate and potassium bromide, 15 gr. (1 g.) of each four-hourly per rectum, was begun. Any reduction of this dose at once resulted in a return of the spasms. For the first 24 hours no attempt was made to pass a nasal catheter, and fluid was given per rectum—2½ oz. (70 ml.) of water two-hourly.

On the second day four-hourly nasal feeds of expressed breast milk were given, but the water per rectum was continued, to guard against dehydration. For five days the whole of this quantity was retained. On the third day penicillin was reduced to 100,000 units four-hourly, and sedation continued. It was now found that the child could swallow, and part of the feeds was given by syringe. As soon as the child tired of swallowing, the tube was passed to complete the feed. On the fifth day he was sucking the syringe strongly; part breast-feeding was begun; phenobarbitone, 1 gr. (65 mg.) four-hourly, was substituted for bromide and chloral; and rectal fluids were discontinued. On the seventh day he was fully breast-fed and phenobarbitone was discontinued. He was discharged in good condition on the ninth day. Two days later he was seen at the clinic. He was then perfectly well and there was no residual stiffness.

CASE 2

An African girl aged 9 days was brought to hospital because she was unable to suck. The child was crying continuously, with risus sardonicus, clenched fists, stiffly extended legs, and taut abdomen. Handling produced convulsive arching of the spine. The umbilical wound was 1½ in. (3.1 cm.) across, moist, and filthy. Her temperature was 100° F. (37.8° C.) and pulse 134. Her heart and chest were normal. She was admitted at once (February 13, 1951). A.T.S. was not obtained till February 17, when 100,000 units was given. Treatment was carried out on exactly the same lines as in Case 1, but the violent reactive spasms remained unabated for seven days, although the child was quiet unless touched. It was necessary to aspirate four-hourly, or more frequently, with a rubber mucus catheter, the nurse summoning medical aid for this purpose each time the child became cyanosed or showed difficulty in breathing. Without these ministrations she would undoubtedly have died. Passing the catheter to the back of the mouth and directing it to the epiglottis was made difficult by the jaw trismus.

On February 19, as the temperature had not responded to penicillin, "aureomycin," 250 mg. four-hourly, was substituted. From this time onwards the improvement was marked and steady, except for one setback. During a nasal feed on the 21st the child suddenly collapsed and ceased to breathe. She was restored by artificial respiration and nikethamide. No feed had been inhaled, and the collapse may have been due to vagal inhibition coupled with respiratory spasm. Curiously enough, the child appeared much better the day after this episode. The aureomycin was now reduced to 120 mg. four-hourly. On February 22 all reactive spasms had ceased and the child could be handled gently without arching of the spine resulting. Nevertheless the whole body remained stiff, especially the legs, which were all the time held stiffly extended except in sleep, when they relaxed slightly. The fists remained clenched and the head retracted. Phenobarbitone, 1 gr. (65 mg.) four-hourly, was substituted for the other sedatives. Massage and movements were started, and in eight days the limbs were back to normal. The aureomycin was discontinued on February 22 (total 3,000 mg.).

COMMENT

Only one dose of A.T.S. was given owing to local shortage. The successful outcome in Case 2, which was in all respects extremely severe, suggests that delay in giving A.T.S. need not prove fatal. It seems logical to give large doses of penicillin or of a sulphonamide, because septicaemia is a strong probability. It is interesting to note the response to aureomycin in Case 2. The very high fluid intake would seem to be necessitated by the muscle spasm, which no doubt increases the body's needs. It may possibly help to prevent serious consequences from the heavy sedation. It is certain that in Case 2 the patient would have died from pneumonia, if not from asphyxia, had she not been aspirated frequently.

MARY E. EGERTON, M.B., B.S., M.R.C.O.G.

A Combination of Congenital Anomalies

It is well known that the presence of one congenital defect in a person should make one examine for the presence of other anomalies. The following case illustrates this fact.

CASE REPORT

A female Bantu child weighing 4 lb. 5½ oz. (2 kg.) was born in the maternity section of Baragwanath Hospital on September 26, 1950. She was premature, of approximately 36 weeks, and delivery was very rapid. She was noticed to be blue from birth. She did not cry or breathe after birth, but the heart was beating strongly. Lobeline was given by injection, the air passages were cleared, and oxygen was administered. She soon started to breathe, but remained

extremely cyanotic. The placenta was circular in shape and appeared to be normal. The umbilical cord was centrally inserted in the placenta, but was only 8 in. (20 cm.) in length.

The baby was the second infant of the mother, who gave no history of any illness during this pregnancy.

On examination the patient was seen to be a newborn female infant showing well-marked cyanosis, especially around the lips and tongue. Her rectal temperature was 97.8° F. (36.6° C.). The umbilical cord stump appeared normal and healthy, with no evidence of sepsis or bleeding. The infant had supernumerary nipples placed in a line between the axilla and groin of each side; there were three extra nipples on the right side and four on the left (Fig. 1).

The fingers and toes were longer than normal. There was a flexion deformity of the second, third, and fourth right fingers and of the third left finger (Fig. 2). The palate was highly arched. No obvious anomaly of the eyes was noticed. The heart rate was 136 a minute. Clinical enlargement of

the heart was present. No thrills or murmurs were detected. Nothing abnormal was found in the lungs. Neither the spleen nor the liver was palpable.

Investigations.—A blood count showed: haemoglobin, 24 g. % (Sahli); erythrocytes, 6,780,000 per c.mm.; leucocytes, 5,100 per c.mm. (neutrophils 39%, monocytes 12%, lymphocytes 37%, eosinophils 10%, basophils 1%, plasma cells 1%); P.C.V., 74%. The red cells showed anisocytosis and an occasional polychromatic staining cell. One nucleated red cell per 100 leucocytes was observed.

The standard Eagle test was negative. An electrocardiogram showed: rate 150, normal sinus rhythm, heart vertical in position; and right ventricular dominance. On radiological examination the heart was much enlarged, with the toe considerably elevated. On screening, there was well-marked enlargement of the right ventricle. There was a fusion anomaly of the tenth and eleventh right ribs. The skull and spine were normal. Elongation of fingers was noted, with the deformities of the second, third, and fourth right and third left fingers.

At this stage the case presented as one of supernumerary nipples, partial arachnodactyly, minor fusion anomaly of two ribs, and cyanotic congenital heart disease. The exact type of cardiac defect was discussed with the following differential diagnoses in mind: Fallot's tetralogy, transposition of the great vessels, common truncus arteriosus, and tricuspid atresia. The last-named was dismissed as a diagnosis in view of the electrocardiographic finding of a right ventricular dominance and of the x-ray evidence of enlargement of the right ventricle: in tricuspid atresia one finds a left ventricular enlargement with left dominance in the electrocardiograph.

The child remained cyanotic until she died on the sixteenth day of life. Throughout this period no murmurs were detected on frequent careful auscultation of the heart.

At necropsy cyanosis was present. The accessory nipples were noted, as were also the long fingers. The palate was highly arched. The lungs, bronchi, and trachea were normal. The heart was enlarged, especially the right ventricle. A high ventricular septal defect was present over which the aorta was straddled. The aortic arch was right-sided. No evidence of a ductus arteriosus was found. An extreme degree of pulmonary stenosis was present. The oesophagus, stomach, and intestines were normal, as were the liver, spleen, and pancreas. The renal system showed the presence of a typical horseshoe kidney. The brain was normal. The fusion of the tenth and eleventh right ribs was noted.

The diagnosis was, therefore, one of multiple congenital defects: supernumerary nipples, partial arachnodactyly, Fallot's tetralogy with a right-sided aortic arch, horseshoe kidney, and fusion of two ribs.

COMMENT

This case illustrates a combination of congenital anomalies, and particularly that of supernumerary nipples and arachnodactyly with congenital heart disease, as mentioned by Paul Wood (1950) and Brown (1939). Here, in addition, we have the kidney anomaly and the minor rib abnormality. The Fallot tetralogy is associated with a right aortic arch, which association occurs in about 20% of cases.

My thanks are due to Dr. J. D. Allen, medical superintendent, for permission to publish this case; to Dr. P. Catzel for the photograph; to Dr. M. J. Meyer, X-ray Department, for radiological services; and to the obstetrical department, Baragwanath Hospital, for permission to use their case notes. I am also indebted to Dr. J. Higginson for the necropsy findings and to Dr. H. Hirsch for laboratory investigations.

BLOOD TRANSFUSION

Blood Transfusion in Clinical Medicine. By P. L. Mollison, M.D., M.R.C.P. With foreword by Sir Alan N. Drury, C.B.E., F.R.S. (Pp. 456; 59 figures. £1 17s. 6d.) Oxford: Blackwell Scientific Publications. 1951.

Remarkable developments in immuno-haematology within the last ten years have made the terminology used by blood-group research workers almost unintelligible to the general clinician and even to the clinical haematologist. Like the specialists in blood coagulation, those who devote their lives to a study of the blood groups talk a language of their own. This is probably inevitable in the face of such rapid expansion in so specialized a field, but the difficulty remains that much information which may be most useful to those engaged in clinical transfusion work tends to be lost in a wealth of academical detail which is of little practical importance and at times somewhat precious.

This book indeed does a great deal to bridge the gap between the clinical and academic aspects of blood-group and transfusion work. But it is not easy reading. There is much rather selected documentation and a good deal of cumbersome cross-reference. From the clinical aspect some of the subject is out of balance, but the work as a whole deserves and richly rewards close study.

The subjects first discussed include the survival of the different components of transfused blood, the estimation of blood volume, and the use of transfusion in haemorrhage, in anaemia, and in studying the life span of red cells. These chapters would be more helpful to the clinician if, in conformity with the title, the emphasis had been on clinical problems rather than research methods. For example, the use of transfusion in "shock" deserves more than twenty lines (p. 74) together with a few pages (p. 67 *et seq.*) on the role of haemorrhage in "wound shock"; both sections are all too brief and somewhat uncritical accounts of the work of others. Yet transfusion when intelligently practised and applied with the judgment which develops with experience is universally acknowledged to be one of the most life-saving clinical measures in treating the circulatory failure loosely called "shock" which is so common in times of war, in cases of injury, including crush injuries, and burns (dismissed in two and a half pages). Here indeed the author might well have spread the net wider to include references to some of the excellent clinical papers, rich in life-saving practical points, published by young civilian and Service transfusion officers who had extensive experience during the last war. Again, from the clinical point of view, the use of transfusion in the blood dyscrasias and in haemorrhagic diseases is very superficially discussed: one looks in vain for a critical appraisal of the value of transfusion, views about indications or contraindications, and practical advice about amount, speed of administration, frequency, and the merits of the different fluids available. One looks in vain also for some succinct and practical recommendations for the immediate and long-term treatment (not even indexed) of incompatibility to supplement the few paragraphs on the treatment of anuria which are submerged in the chapter on haemolytic transfusion reactions.

In contrast, on the academic side, the book contains a most informative detailed discussion on the techniques and the uses of blood-volume determination, but this subject seems hardly to warrant 27 pages in a book which is devoted to clinical medicine and which has indeed so wide a general medical appeal.

The chapters on blood groups, iso-antibodies, and grouping techniques are excellent, for here the author is writing on a subject in which he is an acknowledged expert. It is noteworthy that the ABO system, believed to be under-

stood fairly completely 20 years ago, is now the one in the discussion of which the author is least happy. Transfusion reactions and their investigations are fully and competently discussed, while the last two chapters, devoted to problems in newborn infants, are invaluable and contain much information not concisely available elsewhere.

This book is strongly recommended to those who practise transfusion and wish to do so with a fuller understanding.

LIONEL WHITBY.

SOVIET GENETICS

Soviet Genetics. By Alan G. Morton, B.Sc., Ph.D. (Pp. 174. 15s.) London: Lawrence and Wishart. 1951.

This book purports to present without prejudice the general theories of Soviet biology on which present-day Russian plant-breeding methods are based. For this purpose the author has delved assiduously into a good deal of the Russian literature. The book, however, is an account of what the Russians claim, though there is practically nothing that we do not already know about this through the admirable summaries given in *Plant Breeding Abstracts*. If these claims are true, the methodology of workers in non-Soviet countries is out-moded and superseded, and modern genetics, which is by far the most quantitatively exact branch of biology, becomes a tale told by an idiot.

There are strong reasons for rejecting some of the claims. One of the most fantastic is that made by Ter-Avanesjan about cotton hybrids. He chose as a mother plant a variety of American Upland cotton (*Gossypium hirsutum*) which had four recessive characters: green leaves, short internodes, spotless petals, and absence of yellow filaments. Two paternal forms were used; one was a *hirsutum* carrying dominant red leaf. The other was a *barbadense* carrying recessive green leaf, dominant long internodes, spotted petals, and yellow filaments. In the experiment the female flowers were first pollinated by 10 pollen grains of red-leaf *hirsutum*, and then by a large quantity of *barbadense* pollen at intervals from 30 minutes to 4 hours after the first pollination. The three-hour series gave 28 plants, of which 8 showed dominant red leaf from *hirsutum* combined with dominant long internodes and yellow filaments from *barbadense*. The dominant petal spot of *barbadense* did not appear. This means that an egg cell was simultaneously fertilized by two pollen grains, each bearing different dominants. Mr. Morton concludes that this double-paternal fertilization necessitates a "fundamental reconsideration of the nature of sexual fertilisation." This would not be the view of any non-Communist botanist outside the Soviet Union.

The reviewer was the first to undertake this kind of experiment with cotton. It is a standard procedure for obtaining difficult interspecific hybrids. Between 1928 and 1934 many thousands of mixed pollinations were made—a great many at the alleged critical 3-hour interval. The plants obtained were either *hirsutum* hybrids or *barbadense* hybrids, with no sign whatever of double paternal fertilization.

The fact that self-fertilization leads to loss of vigour in many plants and that even in plants which are usually self-fertilized, such as wheat, varietal crossing of heterogeneous forms will result in increased yields is regarded by Soviet workers and evidently also by Mr. Morton as new and revolutionary. A vast body of information was available on this subject long before Lysenko came on the scene. We know now that some single genes can give heterosis in the heterozygous phase. What the Russians should do is to convert wheat into a cross-fertilizing plant, which would enable hybrid vigour to be exploited.

It is clearly uneconomic—if such a word exists in Russian—for crossing of cereals to be done by hand on a large enough scale, though it was done with cotton in the West Indies as early as 1913.

The serious reader who wishes to know about Soviet genetics will have to engulf whole chunks of pure

Communist propaganda. All books by Russians or about Russians are exasperating, and this one is no exception to the rule. Russian genetics may be described as a mixture of the blatantly fraudulent, the naive, the nationalistic, the obvious, and perhaps in rare cases the interesting and novel. The author is not able to separate the ingredients of this "olla podrida."

S. C. HARLAND.

SOVIET PSYCHIATRY

Soviet Psychiatry. By Joseph Wortis, M.D. (Pp. 314. £1 18s. 6d.) London: Baillière, Tindall and Cox. 1950.

Soviet psychiatry is dominated by the figure of Pavlov. In the terms of Pavlovian physiology the neuroses are intelligibly described as disturbances of cortical function produced by the breakdown of conditioned reflexes under excessive or conflicting stimuli. This mode of approach has found a number of followers in Britain, and proved especially useful in the clinical analysis and treatment of the acute neurotic reactions of wartime. Pavlovian concepts are, however, also applied in Russia to the endogenous psychoses. Schizophrenia, for instance, is regarded as a depression or inhibition of cortical function with the partial escape of lower centres from the control of the upper ones, with consequent development of such symptoms as stereotypies. Together with the physiological approach, Soviet psychiatry also favours psychotherapy in the form of persuasion, re-education, and social therapy. Neurotic symptoms may be due to a conflict between the ideas implanted in the course of a faulty (e.g., insufficiently Communist) education and the demands of society in the Communist world. Treatment therefore will be along those lines. Russia was one of the first countries to take up with energy the insulin treatment of schizophrenia, but it also encourages the pedagogic treatment of nervous symptoms in re-educative therapies. Freud and the unconscious are almost totally disregarded, and, though Freud himself is not without honour, psycho-analysis is obsolete. The treatment of the neurotic child is almost exclusively along pedagogic lines and in the hands of teachers; emphasis is even more on prevention and the treatment of causes than on sick individuals.

Dr. Wortis is to be congratulated on having provided a very useful summary of psychiatric development in Russia. His task was not easy, for he had to rely exclusively on publications. No personal visit to Russian centres of teaching and research was possible. The total impression one gains is that Russia has made enormous advances in the provision of adequate medical services since Czarist days, that the clinical practice of psychiatry and the organization of treatment are of a sound standard, but that little new work is being done along research lines. Original thought, in psychiatry as elsewhere, has to be along the lines laid down by dialectical materialism.

ELIOT SLATER.

E.N.T. FOR GENERAL PRACTITIONERS

Ear, Nose, and Throat Diseases for the General Practitioner. By William McKenzie, M.B., B.Chir., F.R.C.S. (Pp. 136; 2 plates and 9 diagrams. 9s.) Edinburgh and London: E. and S. Livingstone Ltd. 1952.

In my opinion this is the most useful little book on otolaryngology strictly for the general practitioner that has ever been published. I may be prejudiced in its favour—for the author, in his preface, attributes its origin to a remark I once made to him—but I do not think I am. It is intended for doctors whose otolaryngological equipment consists of a tongue depressor, a torch, and an auroscope, and rightly avoids elaborate descriptions of views in the laryngeal or post-nasal mirror. The author points out that a careful history combined with a general examination may often prove as informative as any specialist's report, and makes a plea for more help in the doctor's letter about the background of the patient he refers to the specialist—how

the patient lives and whether he is happy may well decide the whole course of treatment.

The book is full of vivid and illuminating descriptions of cases, and the author is downright and opinionated in the advice he gives, so that no practitioner will be in any doubt about what he ought to do in these frequently troublesome conditions. That is not to say that every otolaryngologist will agree with all his opinions. For example, transillumination of the nasal sinuses is more handy for the practitioner than radiography (which the author much prefers) and very nearly as accurate. Some prefer a comparatively blunt nasal or sinus forceps to the very sharp von Graefe knife, which the author favours for opening a quinsy. It was much less than "a century ago" that two or three cases of tuberculous laryngitis were to be seen at every throat clinic. The author is perhaps over-optimistic about the results of the fenestration operation. I am not convinced about the value of audiographs in a handbook for the general practitioner, though the author points out that for some years he has always included a copy of the audiograph in his report to the doctor of a deaf patient, and perhaps the general practitioner ought to get accustomed to understanding them. And the only excuse for the two plates is that they include photographs of a very pretty R.A.F. nurse.

Mr. McKenzie is very sound and conservative in his discussion of the tonsils-and-adenoids problem, and comes to the conclusion that, in spite of the many criticisms of the operative treatment of them, more children need tonsillectomy than get it. There are excellent accounts of allergic rhinitis and of nasal sinusitis, sensible reviews of acute otitis media, mastoiditis, chronic middle-ear suppuration, and of vertigo and Ménière's disease, and a sound chapter on malignant disease of the nose and throat. The fifteen chapters end with a useful one on prescriptions and a rather brief index. At the price of nine shillings this handbook, which is really suitable for the pocket, is the best value for the general practitioner's money that has been seen since the war.

R. SCOTT STEVENSON.

DOCTORS' ANTHOLOGY

Doctors By Themselves. An Anthology compiled by Edward F. Griffith, M.R.C.S., L.R.C.P. Foreword by Lord Horder. (Pp. 614; illustrated. £1 1s.) London: Cassell and Co. 1951.

An anthology is a bouquet of the flowers of literature united by some common pattern or joined together by something which makes the posy a harmonious whole. In this book, as the title suggests, unity is provided by the fact that all the contributions come from the pens of medical men, or at least from medical sources. Dr. Griffith has made an interesting and varied collection of extracts calculated to please both doctors and laymen. He has spread his net wide and gathered wit and wisdom from ancient and modern, from old and young, from grave and gay, and the thoughts are expressed both in prose and poetry. The book is divided into five sections dealing respectively with the doctor's work, his amusements, his troubles, and his views on life and philosophy. Limiting the anthology to the writings of medical men excludes such interesting material about medical matters as one finds in *The Anatomy of Melancholy*, and in some places second-hand relations of good stories have for the same reason been substituted for original sources, yet here is plenty of good material to satisfy anyone but a carping critic. It is indeed just the book to have at one's bedside to be dipped into as a prelude to sleep or as a solace for the waking hours.

The value of the book is enhanced by the many photographs of distinguished authors and the thumb-nail biographies of several hundred contributors. In addition, the list of sources will be useful to those who wish to consult the originals of the various extracts. We can recommend this as a delightful book, which incidentally has an entirely appropriate epilogue. If there be one extract which we think will please every doctor it is that numbered 801.

SATURDAY MARCH 1 1952

NOTIFICATION OF DISEASE

Seventy years ago opposition to the notification of infectious disease centred round the objection of medical men to any form of compulsion and the fear that it would lead to a destruction of confidence between doctor and patient. No one questioned the benefits, but the alternative, voluntary notification, was already falling into discredit. The medical officer of health for Birmingham complained that :

Instead of the medical man reporting every case of preventable disease, he reports only such as he chooses ; he will report for instance the case of a domestic servant whose presence in a large and respectable family is considered objectionable, and whose removal is therefore desired, and she is removed to the hospital accordingly, but the next case he may for special but insufficient reasons decline to notify.¹

The social conditions thereby revealed have gone, together with the fear of an inquisition by the M.O.H., who no longer has to defend himself by saying, "To assume that, the moment a medical practitioner becomes a medical officer of health, he forgets professional obligations and loses the instincts of a gentleman . . . is not only absurd but opposed to experience."¹ The objection to publishing the secrets of the sick-room was met by placing the obligation to notify on the head of the family, the nearest relative, or any person in attendance on the patient. There it remains, although it is exceptional to-day for anyone other than the medical practitioner to notify.

In the intervening years compulsory notification has extended to include many, but not all, transmissible diseases. Some are notifiable under the Public Health Act of 1936. Others—for example, measles, whooping-cough, ophthalmia neonatorum, and puerperal pyrexia—are notifiable under regulation. A local authority may, with the consent of the Ministry of Health, make a disease locally notifiable by resolution. Since 1944 the accuracy of the statistics of notifiable disease has been increased by taking into account subsequent amendments of diagnosis, but it is clear that the extent of notification is variable. Thus Percy Stocks² estimated that notifications after correction of diagnosis provide a sufficiently accurate

picture of acute poliomyelitis, meningococcal meningitis, and diphtheria, but measles is only about two-thirds notified, whooping-cough between a quarter and a fifth, respiratory tuberculosis about nine-tenths, and pneumonia from a third to a quarter of all ages but varying greatly with age.

While the ethical objections were being met and the legal and administrative framework for compulsory notification established, the methods of prevention, diagnosis, and treatment were already beginning to change. So also were the social habits of the people, and the conditions which notification was intended to meet have undergone radical alteration. There can be few doctors now who hurry from the case of erysipelas to the delivery-room. For that matter the incidence of both erysipelas and domiciliary confinement has greatly declined. Ophthalmia neonatorum and puerperal pyrexia are to-day the mere shadows of their former selves, cerebrospinal fever quietly changed its name in 1949 (by regulation) to meningococcal infection, and encephalitis lethargica has disappeared unmourned into the hold-all of acute encephalitis. Diphtheria has become such a rare disease that an epidemic of 37 cases, with four deaths, is sufficiently unusual to warrant special mention in the annual report of the Ministry of Health. The popular fear of the isolation hospital and its ambulance has gone, and the practitioner must now be prepared to advise on such matters as the merits of combined immunization against whooping-cough, diphtheria, and tetanus, and the advisability or otherwise of embarking on this during the poliomyelitis "season." Similarly the requirements of the community have changed. Knowledge of the presence of infectious disease is no longer a matter of concern only to the local sanitary district but is linked on the one hand with international health and on the other with records of morbidity.

The truth is that the notification of infectious disease is not the simple question it used to be. If its main purpose is to protect the community its value in its present form is doubtful. The clinician, for example, with his interest in speedy diagnosis and efficient treatment, can see little point in notifying a disease such as scarlet fever of whose existence as an entity he is sceptical. The medical officer of health, shorn of clinical responsibility for the very conditions which brought him into being, may resignedly play the part of postman, although he knows that many returns are incomplete. The laboratory worker, on whose shoulders rest more and more the burdens of diagnosis, has no responsibility to notify. The research worker seeking accurate information devises his own machinery for obtaining this. Meanwhile,

¹ Hill, A., *Trans. Soc. med. Offr. Hlth*, 1883-4, 186.

² Stocks, P., *Amer. J. publ. Hlth*, 1950, 40, 670.

questions of vital importance to the community go unanswered. How real, for example, is the relationship between "scarlet fever" and rheumatic fever? How should food-poisoning be defined? Should cancer be made notifiable? Indeed, many more questions can legitimately be asked now than was the case when notification was the subject of controversy 70 years ago.

We need to inquire again which diseases should be notifiable and for what purpose. It is also necessary to ask who should notify and to whom. It was pointed out recently that the guiding principle in collecting morbidity records must not be whether it would be interesting to have them but whether they can confidently be expected to furnish knowledge which will repay the labour of their collection.² So it is with the notification of infectious disease. To be of value it must be accurate, speedy, and complete. Partial information may not only be misleading but may endanger the public health.

PHYSIOLOGY OF SLEEP

In the opening pages of the *Journal* this week Drs. J. W. Lovett Doust and R. A. Schneider describe how with the aid of an ingenious adaptation of a photoelectric cell they were able to make continuous recordings of the oxygen saturation of the blood during some hours of sleep and during the time before falling asleep and after waking up. Twenty-two periods of observation were studied in seven normal subjects. On each occasion an observer was present all night to record changes in respiration and muscular movements, as well as the occurrence of any noises which might affect the depth of sleep. The authors describe seven planes of sleep, of which the 5th, 6th, and 7th are the same, physiologically, as the 3rd, 2nd, and 1st. In the first plane, or stage, the subject is awake, in the second dropping off, in the third he is lightly, and in the fourth deeply, asleep. Arterial oxygen saturation was at 96% in the first, 91% in the second, 90% in the third, and between 87 and 88% in the fourth plane. The fact that there is such a large drop between the stages of wakefulness and sleepiness, with such a relatively trifling one at the later stages, is notable. The levels at which variation in oxygen tension is associated with critical changes in the level of consciousness make a relatively narrow band.

One feature of the experiments which makes the interpretation of results a little difficult is that each subject was standardized individually. The 100% level of oxygen saturation was taken to be that which

was reached after inhalation of pure oxygen until stable readings were obtained. The absolute oxygen tension in the arterial blood may have varied a good deal from subject to subject. Furthermore, it is not possible, at least from these experiments alone, to distinguish between cause and effect. We cannot say, for instance, that normal sleep is brought about by reduction of the oxygen saturation; as the authors emphasize, all that is apparent is that there is a close relation between the two.

Interesting but speculative parallels were drawn between sleep and various forms of mental abnormality. The neurotic patient is often unable to get off to sleep. This may be partly because his emotional tension is reflected in the state of muscular tonus, and he cannot sleep because his nervous system is bombarded by sensory stimuli from the muscles. A later paper is promised which will show that "the oxygen saturation levels of the constitutional schizophrenic are those of the dreamer," and this will not be the first attempt to make comparisons between the psychological and somatic state of the schizophrenic and that of normal sleep. It is, however, easy to bound too far ahead of the known facts in speculation of this kind. As Drs. Lovett Doust and Schneider remark in their article, the physiology of sleep has been studied inadequately for the interest it merits; and there have been no exact physiological studies at all on sleep in mentally abnormal individuals. Quite specific variations are met with clinically. The anxious or obsessional neurotic, who is troubled by painful ruminations, often has great difficulty in getting off to sleep, but once asleep may sleep well. On the other hand, the most typical abnormality of sleep shown by the endogenous depressive is that of early morning waking after dropping off to sleep in a normal way at a normal time. Yet some endogenous depressives, with regular recurrent phases of depression, are abnormally sleepy during each successive phase and sleep for the better part of the 24 hours for days and even weeks on end.

The sleeping patterns of the schizophrenic show, clinically, every kind of variation. It may be that in his waking hours the saturation of oxygen in his blood is relatively low; but his state of awareness is not at all like that of a dreamer or a man in reverie. What one does observe is thought processes which appear to be in every way as lucid and alert as those of the normal, but which are interrupted by mental phenomena of sudden incidence and pathological nature, such as an abruptly experienced hallucination or a break in the logical order of thought. If there is a resemblance between the disorder of consciousness

of the schizophrenic and that of any other state, then it is closest between the schizophrenic condition and that of the epileptic having attacks of petit mal.

Of all mentally abnormal states the one most like that of the dreamer is the acute toxic or confusional psychosis. The somewhat drunken condition of the man waking from sleep is persisted in throughout the 24 hours in these patients. All his day is very like a dream, and the illusions or hallucinations, the difficulties of perception and judgment, the sluggishness of thought are like those to which we are all liable in a hypnagogic state. The delirious patient also shows his specific disturbance of the sleep rhythm—he can neither fall off into a deep and restful sleep, nor can he entirely wake up. It is to be hoped that Drs. Lovett Doust and Schneider will pursue their studies on the physiology of sleep into the psychopathological realm.

ANAEMIA IN PREGNANCY

The hypochromic microcytic anaemia so frequently noted during pregnancy has usually been present before the pregnancy began, and arises from the patient's previous state of health, diet, earlier pregnancies, and severity of menstrual loss. This anaemia is both preventable and treatable, and shows a good response to adequate oral or intravenous iron.

But an even commoner anaemia in pregnancy is the normocytic anaemia associated with increased total blood and plasma volumes (up to 23%), a lesser increase in haemoglobin and red cells, but an unchanged mean corpuscular haemoglobin concentration. It begins after the eighth week and increases progressively until after the sixth month; in the puerperium all the values rapidly return to normal in 7–14 days, although the haemoglobin may be delayed.

This "physiological" anaemia of pregnancy is looked upon by some as without pathological significance, a normal dilution of the blood through increased plasma. Others, however, do not accept this view, particularly since adequate oral or intravenous iron will in most cases relieve the anaemia. All agree that a further fall of the haemoglobin to less than 10 g. per 100 ml. is of more serious import.

Writing in last week's *British Medical Journal*, Drs. Nancy Benstead and G. W. Theobald¹ reported that in a group of 2,000 pregnancies 6.5% of the women had severe anaemia by the sixteenth week, before there was much demonstrable haemodilution, while 60% had haemoglobin values below 12 g. per 100 ml.

Taking similar groups of patients, they confirmed

that the iron-deficiency anaemias responded, as is already well known, to iron therapy, while similar daily oral treatment over a period of eight weeks from the twenty-fourth week completely relieved the so-called "physiological" anaemia in a comparable group of patients. Further, continued administration of iron throughout pregnancy maintained the blood values at normal non-pregnant levels; the addition of molybdenum as a supplement to iron did not offer any advantage in relieving these anaemic patients. The satisfactory treatment of these iron-deficiency anaemias is not always possible by mouth, for some patients do not tolerate oral iron, fail to take the tablets, or else because of various gastro-intestinal conditions the iron preparation may not be absorbed. Consequently the intravenous administration of saccharated iron^{2,3} is a most valuable therapeutic advance in the treatment of iron-deficiency anaemias.

The difficulty of assessing iron deficiency in anaemia of pregnancy by ordinary haematological methods was discussed earlier by Klopfer and Ventura.⁴ They showed that, in true iron-deficiency conditions, besides a reduction in the mean cell-haemoglobin content there is a characteristic pattern of changes, including a fall in the serum iron, a considerable increase in the iron-binding capacity of the serum proteins, and a rise in the level of the serum copper, while the erythrocyte free protoporphyrin is also raised. These are different from the findings in the ordinary normocytic anaemia of pregnancy. During a study of iron metabolism in these patients they found it necessary to give increased amounts of iron intravenously, and considered that in addition to each 24.5 mg. of iron ordinarily required to raise the haemoglobin value by 1% in a non-pregnant woman a further 12.5 mg. was needed to meet the demands of the foetus; but it must not be forgotten that in the non-pregnant anaemic woman it is usual to give a 50% increase on the calculated 24.5 mg. in order to replenish the iron reserves of the body.

In tropical countries, particularly India and Africa, severe anaemias of pregnancy are often macrocytic in type, much more commonly so than in temperate climates. Foy and others⁵ described four varieties of anaemia in Africans. One group was formed by the hypochromic microcytic anaemias with normoblastic marrows, resulting from simple iron deficiency or parasitic infestations. These patients usually respond well to adequate iron or to the elimination of the worms. The other three groups included normochromic normocytic anaemias with or without megaloblastic marrows or giant stab cells, or macrocytic anaemia with megaloblastic marrows and achlorhydria; all of these latter groups respond to liver extracts, folic acid, or "marmite." The megaloblastic, macrocytic anaemias of pregnancy seen in Britain respond to folic acid, but in contrast rarely to crude liver extracts, and never to vitamin B₁₂.

Woodruff⁶ adds a further group of pregnancy anaemias observed in Nigerians going into premature labour, taking a protein-deficient diet and showing enlarged liver and spleen, evidence of liver damage,

and usually a macronormoblastic marrow. The anaemia becomes more severe towards the end of the pregnancy, remaining refractory to ordinary anti-anaemic treatment, and usually remits spontaneously after parturition. This anaemia, which may show some evidence of haemolysis, is associated with increased diameter and thickness of the red cells and resembles the anaemia of malignant malnutrition or kwashiorkor. The frequency of microcytic hypochromic anaemia in Africa is again emphasized by Foy and Kondi,⁷ who indicate that failure of iron absorption or its utilization, blood loss, and the presence of parasites are very important factors to be considered in diagnosis. This is especially so among natives in South Africa, where it may be quite difficult to find iron-deficient diets.^{8,9}

PHOTOSENSITIVITY AND PORPHYRINS

Photosensitivity is an occasional well-known reaction to treatment with sulphonamides, and a number of other drugs may call forth urticarial reactions which at least appear to be aggravated by sunlight. Writing in last week's issue Drs. Frankis Evans and J. Gould incriminate thiopentone. It is natural to recall the photodynamic property of the porphyrins and to consider whether or not these pigments may play a part in all such reactions. Rimington and Hemmings¹ were able to show that the sulphonamides caused a raised urinary coproporphyrin excretion, but the interpretation of this finding was difficult. The extra coproporphyrin might have come merely from the enhanced erythropoiesis replacing red cells lost through the haemolytic action of the sulphonamide. In rats treated with sulphonamide Legge² was unable to find any change in the coproporphyrin of the urine, and the differing results were ascribed to differences in diet.

The photosensitivity seen in pellagra has been widely attributed to porphyrin sensitization, without any supporting evidence such as determination of the light wavelengths involved, but non-alcoholic pellagra does not show any change in urinary porphyrin.³ It is only when alcoholism accompanies the deficiency that coproporphyrinuria is found. Some years ago, Gillman, Gillman, and Brenner⁴ reported that liver biopsy of pellagrins revealed a depository stage in the disease, in which, prior to the deposition of cytosiderin, an intense porphyrin fluorescence was present in the liver cells. They postulated that this was occasioned by the disruption of an intracellular iron-porphyrin complex. By exposing to ultra-violet light patients who had passed through this stage, they were able to demonstrate the reappearance of porphyrin fluorescence in the hepatic cells, although there was no change in the skin lesions or other symptoms of the patients. The South African authors emphasize that massive porphyrin accumulation may occur in the liver without detectable increase in the level of porphyrin in the urine. More recently,

Grinstein, Wikoff, de Mello, and Watson⁵ have observed that ultra-violet irradiation of rabbits poisoned with lead greatly increases their already severe coproporphyrinuria.

The mechanism of these effects is not understood. Metabolic deficiencies may possibly condition the response of any tissue to a toxic substance, and in certain circumstances it may cause the liberation of photo-active agents, such as porphyrins from intracellular haems, which sensitize the tissues to the action of light. Alternatively, the foreign toxin may be changed in the body into a fluorescent derivative, itself capable of acting as a photosensitizer. Phenothiazine administered as an anthelmintic to calves is converted to the photo-active phenothiazine sulphoxide^{6,7,8} and is therefore liable to cause photosensitization. But it hardly ever has this ill effect in sheep, in which the chemical transformation takes place only to a negligible extent.

A careful determination in any patient of the particular wavelengths of light to which the skin is sensitive will often help in identifying the photosensitizer ultimately responsible by indicating its absorption spectrum. Such a spectral survey is always desirable in an investigation of obscure photosensitive states.

EPIDEMIC HAEMORRHAGIC DISEASE IN KOREA

In the past three months some prominence has been given in the lay press to accounts of a new disease which has attacked troops of the United Nations Forces in Korea. The disease is called epidemic haemorrhagic fever or "Songo fever," from the Songo district in Manchuria, where it first attracted Japanese attention in 1939. It has also been called "Kokka disease," "Korin fever," and "Nidoko disease," from the names of places where some of the earlier outbreaks occurred. Some investigations were carried out by the Japanese during the second world war and have been reported in Japanese medical literature.

It is generally thought to be a virus disease which is probably transmitted to man by the mite *Laelaps jettmari* Vitzthum. The host of the mite and the probable reservoir of the virus is a field-mouse *Apodemus agrarius*. The disease in man is characterized by fever, myalgia, albuminuria, and a petechial rash. In the more severe cases there may be haemoptysis, haematemesis, haematuria, and melaena. The fever usually lasts about seven days, and in a favourable case there may be complete recovery within 14 days of the onset. In other cases a low-grade fever, palpitation, insomnia, and anorexia may persist for some weeks. The fatality rate in Japanese cases was about 13%. The condition is seasonal in incidence and occurs most frequently in May and June, and October and November. The treatment is symptomatic, and it is reported that antibiotics and sulphonamides have been ineffective.

It will be observed that the epidemiology of this disease closely resembles that of scrub typhus, although the clinical features present considerable differences. The preventive measures are similar to those for scrub

typhus. Long trousers are worn, impregnated by a miticidal agent. As far as possible troops avoid sites where rodents and mites are to be expected, and intensive measures for the control of rodents are put into operation. These include bulldozing, scraping and burning, and the application of miticidal agents.

The most recent information is that some 60 suspected cases of the disease have occurred in troops of the Commonwealth Division. The mortality has been less than 10%. The United States Army medical authorities in Korea are carrying out intensive research on this disease, and have claimed that transfusions of blood from convalescent patients shorten its duration.

VARIOLA MINOR

Since 1934 this country has enjoyed a relative freedom from both varieties of smallpox. Such a statement may seem an exaggeration to those involved in the outbreaks of the major variety of the disease which have occurred in the last few years. Nevertheless these have all been introduced from without, and, although the outbreaks were a legitimate cause of national concern, the energetic measures of public health departments have rapidly subjected each incursion. The news that a focus of variola minor may have been detected in south-east Lancashire (see p. 498) is disquieting, mainly for two reasons—first, because the mild nature of the illness which this type of variola causes means that cases are easily missed or accepted as unusual forms of chickenpox; and, secondly, because the low vaccinal state of the population might well provide the soil in which the disease could again become endemic, as it was during 1928 to 1934.

In such circumstances awareness of the infection and its early recognition constitute the best means of control. What advice can be offered to the general practitioner who may be faced with such cases? Obviously confusion with chickenpox is the likeliest error, and in this connexion two broad generalizations may be made. It should be remembered, first of all, that in chickenpox the rash tends to dominate the clinical picture from the onset. Very few cases show much in the way of a prodromal illness, and in the few where it is present the symptoms are not severe and the duration is short. Then again it may be stated that it is most unusual for the rash of chickenpox to show a preference for the extremities. The patient should lie in bed with arms and legs extended and without covering: the rash will be seen to diminish in quantity as the eye moves out from the centre of the body. On the other hand, when the rash is most prolific on forehead, arms, and legs; when there is more rash on the lower half of the limb than on the upper; and when the palms and soles are involved in a rash which is otherwise sparse, then smallpox is possible and expert advice must be sought. In other words, variola minor shows most of the characteristics (apart from severity) of variola major—namely, a rather marked prodromal illness which may suggest severe influenza or pneumonia and may last for two to four days, a rash which has a centrifugal character, and individual elements which, though they are smaller and

less regular in shape and size than in major smallpox, progress rather slowly from stage to stage. Cropping, characteristic of chickenpox, is unusual.

Such dogmatic generalizations make it all sound very easy. Unfortunately many cases make even the expert shake his head, and it is well to emphasize that in such cases judgment must not rest on an assertion of clinical opinion. Perhaps in no other field can the virus laboratory give such rapid and reliable advice as in the diagnosis of smallpox. An attempt at virus isolation must now constitute an essential step in the investigation of every doubtful case.

Certain other questions will naturally be asked. Does vaccination against smallpox afford complete protection? Successful vaccination affords immunity against both variola major and minor; but the important word is "successful." The so-called "immune" reaction must not be relied upon, and, when smallpox is about, should demand revaccination with freshly prepared lymph on to a new skin site. Can variola minor produce the major variety? Up to the present time no difference between the two viruses has been demonstrated, yet every piece of evidence supports the view that the diseases breed true. Lastly, are there any new methods of treatment? So far as the virus stage of the infection is concerned—and this covers the prodromal period and the outcrop of the rash—there is no specific treatment. Anderson and his colleagues have shown that in the major form of the disease early administration of the new antibiotics will not save the life of the patient who is severely infected by virus, but will limit secondary bacterial infection and promote rapid healing of the lesions in those who escape the worst form of the disease. Chemotherapy has therefore a definite place in variola minor. It should be appreciated that the type of bacterial secondary infection may well vary from patient to patient and from place to place, so that bacteriological examination of the pustular material is desirable. For general purposes the newer antibiotics would seem best because of their wide range of activity.

NEW TREATMENT FOR TUBERCULOSIS?

Last week-end a series of press conferences in New York gave the first news of three new drugs which are claimed to be extremely effective against tuberculosis. They are close relatives of nicotinamide, the anti-pellagra vitamin, and their antibacterial activity has presumably been discovered by following out the well-known theory of Fildes and Woods that vitamin-like chemicals are likely to interfere with the normal metabolism of the vitamins needed by bacteria for growth: thus sulphanilamide competes with and displaces the vitamin *p*-amino-benzoic acid and inhibits bacterial growth.

The new drugs are said to be isonicotinic acid hydrazine (the most active), its glucosyl derivative, and 1-isonicotinyl-2-isopropyl hydrazine, which have been prepared in the laboratories of Squibb and Hoffmann La Roche. Both these firms, the National Tuberculosis Association, and the New York Commissioner of Hospitals have given interviews to report the effects of the drugs on the 190 patients so far treated. These,

as reported at length in the *New York Times* of February 22 and 23, are our sole source of information so far, and no details have yet been given to any medical conference or medical journal.

The tuberculous patients, at Sea View Hospital on Staten Island, were selected because they had not responded to streptomycin or *p*-aminosalicylic acid, and were given the new drugs by mouth, after tests on experimental tuberculosis in mice and guinea-pigs had proved promising. The effects were said to be spectacular. Within a week the patients, "all of whom were emaciated and had been refusing food, developed ravenous appetites. One ate as many as 11 eggs for breakfast. A female patient who had declined from 185 lb. to 97 lb. regained 84 lb. in nine weeks. Another gained as much as 95 lb. in a similar period." Many also had temperatures ranging from 100° F. (37.5° C.) to 105° F. (41° C.), which fell to normal after two or three weeks of treatment. Improvement was shown not only in pulmonary tuberculosis but in disease of the larynx and intestine.

Full case histories and proper clinical reports with controls will be awaited with much interest. Much longer experience of treatment will also be needed before any true estimate of the value of the new drugs can be made. The drugs are not yet commercially available, and in the meanwhile we can only watch with cautious enthusiasm for further news.

UNIVERSITIES AND MONEY

It was cheering to learn on February 21 that at this time of financial crisis the Chancellor of the Exchequer has been able to find more money for the universities. This year, which is the last of the old grant, they will have rather less than £17m. between them. Under the new proposals they will get £20m. next year, and increases each following year to £25m. in 1956-7, which, with increasing costs, should mean that they will just about be able to maintain their present activities. This is satisfactory, since the last five years have seen an enormous expansion in higher education, and it is doubtful whether the general facilities require much further increase. The University Grants Committee's interim report on the years 1947-51,¹ just issued as a White Paper, notes in its introduction that during these five years £17m. worth of new buildings have been completed, while the student population has increased by 70% and the full-time university staffs from 5,561 to 8,490. It comments that no further increase in numbers of students can be expected in the immediate future without reducing university standards. The next step in fact is one of consolidation, in particular of making sure that students are studying the right subjects. It will be unfortunate if arts graduates, for example, are produced in numbers far in excess of the suitable jobs awaiting them, leading to unemployment and discontent, while the number of dental students remains well below the level required by the Health Service. The Committee points out that there used to be an average of 350 new dentists a year before the war,

and although this figure is now about 600 a year the Teviot Committee recommended 900, and there is clearly need for further expansion. As one contribution towards this expansion, the provision of more teaching staff, the Nuffield Foundation has started an interesting scheme of scholarships and fellowships to induce medical graduates to change over to teaching and research in dentistry, which has been relatively neglected. An advertisement giving details of the openings of this kind appeared recently in our columns.²

Although in accordance with the views of the Goodenough Committee there has been no increase in the number of medical students in the past quinquennium, the report has some interesting facts on the quantitative growth of medical education. Last year the medical schools received nearly £3m. of public money, of which the British Postgraduate Medical School in London took over £400,000. Fifty-five new full-time clinical professorships have been created (three for the Postgraduate School), and the full-time academic staffs of nearly all the medical schools have increased. At Guy's, for instance, the staff has grown from 34 in 1946 to 100 last year, at Bart's from 20 to 50, at the Middlesex from 51 to 74.

THE ROSS INSTITUTE INDUSTRIAL ADVISORY COMMITTEE

The Ross Institute Industrial Advisory Committee was formed in 1928 "to keep Industry in touch with Science, to make the Tropics healthy, and to expand the markets of the world." It includes representatives of tea, rubber, sisal, sugar, mining, and oil interests in all parts of the world. They met on February 21 to hear Professor George Macdonald report the Institute's recent work both in the field—it has field branches in India, Pakistan, and Ceylon, and a new mobile laboratory in East Africa—and in London, where it is responsible for the teaching of tropical hygiene at the London School of Hygiene and Tropical Medicine.

In particular, Professor Macdonald discussed the socio-medical aspects of labour problems in the Gold Coast mines. Some 200,000 people move annually between the relatively healthy but infertile territories of the north and the humid and unhealthy forest belt of the south, where they work on the cocoa farms or in the mines; the prosperity of the colony as a whole is dependent on this migration. The journey of at least 350 miles on foot or by expensive lorry to the labour-sorting town of Kumasi is bad, and many arrive in undernourished condition, approaching exhaustion. It is not surprising that tuberculosis is common: B.C.G. vaccination appears to be a partial solution, but it would need to be part of a Government plan to alleviate the conditions of travel and ensure adequate food from source to destination. Among mine employees there is a core of permanent workers who should be singled out for special observation and protection against the industrial hazards of their work, particularly silicosis. Medical and hospital facilities on the mines are good, but there is need for specialist advice on the industrial hazards of heat, silicosis, and accident.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

WARTS OF THE FEET

BY

L. FORMAN, M.D., F.R.C.P.

Physician, Skin Department, Guy's Hospital

Warts of the feet are a common minor ailment. They may lead to considerable discomfort, and, as they often occur on pressure points, may give rise to incorrect positioning of the foot. They are seen in patients of all ages and both sexes, the maximum incidence being between the ages of 10 and 25. In children minor epidemics occur in schools, the infection being acquired by inoculation of the bare feet in swimming-pools and changing-rooms and when dancing. That warts are contagious is a matter of common clinical experience. One may appear on the physician's finger after contact with the instrument used for curettage, and there is experimental evidence that the causative agent is a virus. The incubation period of the plantar wart is variable, from six weeks to five months, and occasionally as long as a year.

Histopathology

The wart consists of a localized hyperplasia (acanthosis) of the epithelial cells (see Fig. 1). There is an increased rate of division of the basal layers, excited by the overlying infected cells. The latter contain intranuclear inclusion bodies and exhibit "ballooning" of the protoplasm. M. J. Strauss and his colleagues have reported the finding of crystalline particles (Fig. 2) in the inclusion bodies under the electron microscope; these they take to be the infecting virus. The rete pegs become thickened and project downwards, with a corresponding elongation of the papillae carrying the fragile capillaries. The latter are easily ruptured by pressure on the wart, and small haemorrhages are carried through the epidermis to show on the surface as discrete black dots. There is an associated increase in the horny layer.

Strauss and his colleagues noted that the warts which showed the "virus" histopathology differed in clinical appearance from those which did not contain inclusion bodies. The "virus" warts were single or multiple, but not confluent, and surrounded and almost hidden by a collar of horn. When exposed by the removal of horn the wart had a soft consistence and with the curette shelled out cleanly. Warts which did not show the characteristic histopathology were of the superficial dry hyperkeratotic type.

Clinical Appearance

The individual plantar wart is skin-coloured or brown, often speckled with brown or black points of haemorrhage. The surface is rough and irregular, tending to show lobulation in the larger warts. The main mass of the wart may be pressed down into the skin by the body weight and barely show above the surface. In addition a thick collar of horn is formed by the surrounding compressed normal skin. If this collar is trimmed away it will be seen that the skin ridges lead up to the edge of the epithelial mass of the wart and then stop short (Fig. 3). Further paring of the wart will cause pain as the nerve endings between the cells are reached, and soon points of bleeding will indicate the severance of the tops of the elongated papillae. Further dissection causes acute discomfort and free bleeding.

Warts may be single or multiple and occur anywhere on the foot or toes. The pressure areas are commonly involved, as they are particularly likely to pick up infected fragments of horn. Warts may reach 1 cm. in diameter, and often they are grouped with a large wart in the centre and smaller warts as a constellation around, suggesting that the latter

have arisen by inoculation from the "mother" wart. Another arrangement, seen usually in adults, is the so-called "mosaic wart," where a number of small warts, equal in size, compress each other to a polygonal shape. Mosaic warts have a uniform covering of thick horn. The ball of the foot or the heel are the sites commonly affected. This kind of wart indicates multiple invasion and probably low immunity, for it is the type most resistant to treatment.

Differential Diagnosis

Among the common conditions which may be mistaken for plantar warts are corns and callosities. (For a detailed description see the Refresher Course article by Mr. N. C. Lake on "Minor Ailments of the Feet," published on May 5, 1951.) Horny scars left after caustic, surgical, or x-ray treatment of a wart may also be confusing. Because of the thin epidermis and dilated vessels in the atrophied cutis, haemorrhages readily occur which may speckle the horn as in a true wart. Further, the scarred epidermis may be irregular in thickness, the horny cap following the contour to give a rough surface. However, careful dissection will expose the thinned and irregular epithelial base without bleeding, and inspection with a lens after stretching the skin will demonstrate the normal ridge markings. Other localized keratomata rarely cause difficulty, for they are usually multiple. They are either congenital and present on the hands and feet (keratoma punctata) or form part of a general cutaneous disorder—for example, Darier's disease or arsenical keratosis. A pigmented naevus or melanoma appears as a brown or black area with the epithelium stretched and smooth over the surface. If it becomes malignant the increase in size will be noted by the patient, and the epithelium may become necrotic. The malignant melanoma presents as a dark

FIG. 1.—Histopathological features of a plantar wart. Great increase in horn (H); hypertrophy of epithelium and rete pegs (E); elongated papillae containing capillaries (P); cells in the Malpighian layer containing eosinophilic granules and masses in the protoplasm (I); dense deeply staining nuclei containing inclusion bodies, the cell bodies being degenerated and ballooned (N). These cells can be traced through the horn. (Drawn by Miss A. Gretener, of the Institute of Dermatology, University of London.)

FIG. 2.—Crystalline particles from inclusion bodies. ($\times 40,000$). (M. J. Strauss, H. Bunting, and J. L. Melnick, *J. invest. Derm.*, 1950, 15, 433. Reproduced by kind permission.)

brown or black crusted mass, bleeding easily and raised from the surface. (See also Refresher Course article by Dr. H. Gordon on "Cancer of the Skin," published on August 11, 1951.)

Indications for Treatment

Plantar warts in children often subside spontaneously. It is difficult to give an accurate figure for this, but at least 25% will disappear over a period of observation of one year. Even in adults this may occur after two or three years. One could therefore delay treatment in certain cases.

What then are the indications for active therapy? Children may not be allowed to take part in some school activities because of the risk of infecting others. The wart may be painful and lead to disability in walking or playing games. When the wart increases in size and new warts appear, spontaneous healing may be too long delayed.

The aim of any treatment of warts on the feet is that it should be speedy, giving the minimum of pain and disablement. Further, no treatment should be advised that is apt to damage the underlying fibro-fatty tissue to any significant extent and lead to scarring or ulceration.

Single or multiple warts in children, with the features of virus warts, will respond to treatment on any of the lines to be discussed, but the dry, multiple, or mosaic wart of the adult or elderly patient can be resistant and calls for the exercise of the utmost therapeutic ingenuity. The method of treatment chosen will depend on the age of the patient, the type and number of the warts, and the time available.

In a child, when the wart reacts with a considerable inflammatory response it is well to wait four weeks before repeating

FIG. 3.—Plantar wart ($\times 6$) in a child of 9 years, showing the sharp border and interruption of the normal pattern of skin ridges. (From the Photographic Department, Guy's Hospital, London.)

treatment. If successful, the wart will have separated away or be easily lifted off. The epidermis beneath is thin and pink but will soon regain a normal colour and thickness. If no relapse occurs within a month, cure may be assumed. In adults it is wise to wait at least two months before the patient is discharged.

Suggestion

Treatment by suggestion includes buying the wart and burying the coin; applying plants, weeds, and meat, the suggestion being that the living content of the wart is thus transferred. The wide range of agents used has led to the view that suggestion alone will be adequate. The visit to the doctor itself and the act of inspection also suggest strongly to the patient that relief of the warts will be obtained. A plantar wart in a child may involute in the interval between the first inspection and a subsequent visit for treatment. Warts have also been successfully treated while the patient is in the hypnotic state.

Occlusive Strapping

Simple occlusion of plantar warts by strapping carried around the foot and pressing on the wart may be successful. The strapping should be changed every two weeks and the macerated horn and wart substance pared down. D. A. Duthie and D. I. McCallum have recently reported that in 60% of a series of 90 warts so treated the substance of the wart could be removed within one to three months, with cure. They also combined this method with the application of podophyllin in oil.

If the strapping gives rise to irritation of the skin it should be removed and not reapplied, for a strapping dermatitis may extend very widely beyond the original areas of contact.

Freezing

Most plantar warts are treated by physical or chemical agents which damage or destroy the epithelial mass and provoke inflammatory reaction in the skin around.

Freezing with carbon-dioxide snow is a popular, safe, and convenient method. For a small wart or group of warts the stick prepared in the "sparklet" apparatus is adequate; if the wart is larger it can be frozen in segments by the small stick, or a larger stick can easily be prepared. For this the snow is collected from the escaping nozzle of the carbon-dioxide cylinder in a chamois-leather bag and hammered down firmly into a boxwood or plastic mould selected to the size of the wart to be treated. After the horn over and around the wart has been pared down the carbon-dioxide stick is firmly applied, and the wart and the surrounding skin become white and hard. The time of application depends on the size and depth of the wart: from one to three minutes is adequate. With the longer exposure a blister may form within 24 hours. If this is large and uncomfortable it can be snipped in four days, and in many instances the wart riding in the roof of the blister can be detached and the wound dressed. Healing is rapid, with a minimal amount of scar. If blistering has not occurred and after three weeks the wart has not shown any sign of early separation, the snow can be reapplied. There is no contraindication to four or more applications if there is a minimal response in adults. This treatment can be used with confidence for children, in whom the cure rate is 90%; in adults it is 50%.

Liquid oxygen is another convenient agent for freezing plantar warts in the clinic. The temperature of liquid oxygen is -182°C , 125°C lower than that of carbon-dioxide snow. It is supplied in a vacuum bottle and applied on a wool-tipped applicator for periods of 20 to 40 seconds, depending on the size of the wart, until the latter has been well frozen.

Escharotics

The chemical necrotizing agents in common use are salicylic acid, monochloroacetic acid, nitric acid, saturated silver nitrate solution, and the silver nitrate stick. The more

penetrating substances such as monochloroacetic or nitric acid should be used with great caution.

Salicylic acid is used in the form of a 40% plaster cut to the shape of the wart, applied for seven days and then removed. After the macerated horn has been scraped away the irregular and papilliferous mass of the wart will be exposed. The applications are repeated at weekly intervals, and the necrotic epithelium is removed until the granulating cutis is eventually exposed.

Other caustics are used in a similar manner, the period between treatments being determined by the depth of the necrosis. If pain is severe the caustic application should be removed and the area bathed with a mild antiseptic lotion, such as 1% cetrimide or potassium permanganate 1:2,000. Any fluid or pus under the wart should be released and a bland boric ointment applied. There is a definite risk of scarring if caustic applications are allowed to damage the cutis to any degree.

Formalin

A much safer method than the use of escharotics is to fix the cells of the wart with formalin. The wart-bearing area of the foot is soaked in 3 to 5% formalin in a shallow dish for 10-15 minutes once or twice a day for three to six weeks. The only discomfort is dryness and irritation of the skin, but treatment must be stopped if there is any evidence of formalin sensitivity. Soaking in formalin is also to be recommended for multiple or mosaic warts.

Podophyllin

Podophyllin resin is also an effective and safe remedy for plantar warts. It has a selective action on the nuclei of the cells and in a 10-25% solution or suspension in oil produces necrosis of the epithelium. The horn is pared off the wart and the podophyllin suspension in oil applied; it is prevented from spreading laterally beyond the wart by a ring of strapping, and, finally, a covering of strapping is placed on top. Contact with the oil is allowed for 24 to 48 hours, depending on the rapidity of the epithelial necrosis and the discomfort. The soft white epithelium is then scraped away and the treatment repeated every one or two weeks. After 8 to 10 weeks the bulk of the wart will have been removed, leaving a granulating base of cutis. If excessive, the inflammatory reaction should be treated as indicated above.

Surgical Removal

Surgical removal of a wart is rapid, but the injection of a local analgesic into the foot is painful. Excision of a wart should not be done if a pressure area is involved, because the scar will have to bear weight and may be painful. Should there be a recurrence *in situ*—and this may happen particularly in adults—further treatment will be apt to increase the extent of the scar. Scarring is minimal when plantar warts are removed with a curette, and in an adult with numerous warts this is often the method of choice. It can be carried out under a local analgesic, but a short general anaesthetic may be required. The wart is outlined by an incision in the collar of horn and is readily removed with a sharp spoon from the depression in which it lies. The overhanging horny collar may then be trimmed with scissors. Healing is rapid, within a few days, under a simple antiseptic dressing. The results are good, and treatment can safely be repeated if relapse occurs, as it may do even after several months. This is also a safe method for the dry and mosaic wart, which is outlined by the knife-point and carefully and thoroughly scraped away.

Cauterization.—The galvano-cautery can be used to coagulate a wart, and the charred tissue scraped away with a curette. It is doubtful whether this method is any more effective than simple curettage.

Radiotherapy

The use of x rays or radium is the treatment preferred by many dermatologists because it is painless and the patient

is able to continue his normal activities. About 50% are cured with an x-ray dosage of 400 to 600 r, and this is a safe dose to give. Some dermatologists and radiotherapists give up to 1,500 r, but there are warts which are resistant even to this dosage, particularly the dry and hyperkeratotic type in adults. Attempts to cure them with x rays may lead to persistent radio-atrophy or even ulceration. In my view x rays or radium are never indicated in the treatment of children or young adults. Their skins are vulnerable to x rays and they have longer to live, so that there is more opportunity for late permanent atrophy to occur.

Thorium X, which emits most of its energy as alpha particles, is much less likely to cause damage to the deeper tissues. The dosage used has been 2,000 electrostatic units per ml. of collodion, applied at intervals of three weeks for a maximum of four applications. The preliminary removal of horn before each application is important, as the horn has a screening effect. Thorium X has been found to be most useful in the treatment of adults or the elderly when the warts have not responded to caustics, freezing, or to surgical measures, and should be limited to these cases.

There remains the recalcitrant adult case in which treatment by caustics, surgery, and radiation has failed. These patients have been unable to develop any immunity to the wart virus, and it may be worth trying to stimulate antibody production by the use of a wart virus vaccine.

Conclusion

It must be emphasized that the successful management of warts of the feet depends on the ability to make an accurate diagnosis based on careful dissection of a suspected area. If the wart does not respond to therapy which is safe and non-mutilating, it is best to forbear. Discomfort can be relieved by paring the horn and the application of felt or padding.

Next Refresher Course Article.—"Clinical Assessment of Backache," by Mr. J. G. Bonnin.

LOYAL ADDRESS FROM THE B.M.A.

The Secretary of the British Medical Association has sent the following Loyal Address to the Home Secretary for transmission to the Queen:

TO THE QUEEN'S MOST EXCELLENT MAJESTY

*The Humble Address of the President and Members
of the British Medical Association*

MAY IT PLEASE YOUR MAJESTY,

We, Your Majesty's dutiful and loyal subjects, the members of the British Medical Association distributed throughout Your Majesty's Commonwealth and Empire, beg leave to express our deep sorrow at the heavy affliction that has fallen upon Your Majesty, Her Majesty The Queen Mother, and the other Members of the Royal Family by the death of our beloved Sovereign, King George, Patron of the Association.

We beg Your Majesty to be pleased to accept our loyal congratulations on Your Majesty's Accession to the Throne. We pray that Your Majesty's Reign may be long, illustrious, and blest with peace, and we humbly offer to Your Majesty an assurance of our high regard and affection and our unfailing fidelity to Your Majesty's Throne and Person.

Signed on behalf of the British Medical Association,

A. W. S. SICHEL,
President.

E. A. GREGG,
Chairman of Council.

S. WAND,
Chairman of Representative Body.

A. M. A. MOORE,
Treasurer.

Reports of Societies

PRACTICAL EPIDEMIOLOGY

On February 15 three quite different subjects were discussed at a meeting of the Epidemiology and State Medicine Section of the Royal Society of Medicine at 1, Wimpole Street, W.1.

Dr. D. THOMSON began by describing the consequences of the Ministry of Health's decision to require the separate return of cases of paralytic and of non-paralytic poliomyelitis. During 1950 the returns showed that the ratio of such cases remained fairly constant at about 2:1. During the early part of 1951 the same conditions persisted until the 24th week, when there was a sharp change and the cases returned as non-paralytic poliomyelitis began to exceed the cases of paralytic poliomyelitis. From this time until the 37th week of the year this curious change in the ratio continued, and then there was a reversion to the previous approximate 2:1 distribution.

A New Type of Meningitis?

It was suggested that these cases of non-paralytic poliomyelitis returned between the 24th and 37th weeks of 1951 were really part of a distinct epidemic of an unknown disease. The epidemic affected approximately the same age groups as poliomyelitis; the incubation period was of the order of 5-7 days and the duration was quite short. The typical case, apart from severe headache, had a moderate temperature for three to four days, and signs of meningeal irritation. Lumbar puncture showed a pleocytosis (mostly lymphocytes) varying from 10 to 150 per c.mm. Striking features were that many cases had been in contact with each other and that no classical poliomyelitis cases had been seen in the locality for at least twelve months. Some observers had been reminded of cases of sandfly fever, but there was no evidence that any insect vector was involved. The disease could most plausibly be classified as an acute aseptic meningitis. The signs and laboratory investigations did not support a diagnosis of lymphocytic choriomeningitis, nor were the symptoms typical of Bornholm disease.

At the end of the discussion Dr. G. W. A. Dick voiced the opinion of many of those present when he urged that epidemiologists must have more co-operation from laboratory workers; in particular that teams of laboratory workers should be available for the collection of specimens in the field on a scale which was not at present possible in this country. The epidemic was, perhaps reasonably, assumed to be a virus infection, but without quite elaborate laboratory investigations it was impossible even to define the problem, let alone to characterize the nature of the infection.

Reactions to Vaccination

Dr. M. MITMAN gave an account of the reactions which might follow vaccination. Local reactions were of two types—those due to multiplication of the living virus and those due to sensitivity to the virus (dead or alive) and its products.

The susceptible—i.e., the unvaccinated and those whose immunity from previous vaccination had lapsed—responded to the living virus with the typical primary-type reaction, which was maximal after the 7th day.

The partially immune—i.e., those with some residual immunity from a previous vaccination—responded with a modified lesion which was called "vaccinoid" or "accelerated." In fact, its onset was not accelerated and might even be delayed, but because it ran its modified course rapidly its maximum intensity was reached between the 3rd and 7th days. It should not be called an accelerated reaction.

The sensitive, whether susceptible or immune, responded to the virus, dead or alive, with an early reaction on the 2nd or 3rd day which had been called the "immediate reaction of immunity," but was neither immediate nor a reaction of immunity. It had been regarded as the normal reaction of the immune subject, but, as it might occur in those whose immunity had completely lapsed, it should not be called a reaction of immunity. Because sensitivity persisted after immunity had waned, revaccination commonly resulted in a combined early and vaccinoid reaction. While the former was regressing the latter developed; hence the impression that vaccinoid reactions start early. Distinction between sharp early reactions and mild vaccinoid ones was sometimes difficult. Vesiculation commonly regarded as a distinctive feature of vaccinoid reactions occurred in sharp early reactions although the vesicle was clinically different.

The absence of any reaction at all had been regarded as evidence of complete immunity and of a refractory state, but was most commonly due to errors in technique. Technical failures, even by the experienced, were surprisingly common. Immunity from vaccination was of shorter duration than commonly believed. The best practice was to obtain a minimal primary vaccination and to revaccinate at short intervals—one or two years in those subject to special risk. Even if there was no take, the revaccination probably boosted immunity, although serological evidence was required to support that hypothesis.

Precautions against Serum Reactions

To conclude the meeting, Dr. H. J. PARISH, in a joint paper with Dr. L. J. M. LAURENT, discussed serum reactions and serum sensitivity tests. Different authorities gave contradictory advice about the various sensitivity tests. The real problem was to avoid the immediate anaphylactic reaction, which, although very rare, was dangerous and might prove fatal. The practitioner was not concerned about serum sickness of late onset, the case incidence of which had been reduced to about 5% by enzyme-refined serum: rashes were almost always transient and mild. Laurent and Parish deprecated the use of the intradermal test for serum sensitivity. It gave no security if negative, and if positive might needlessly deter the administration of serum. The common assumption that local and general hypersensitivity always ran parallel was wrong.

Explicit instructions were given on how to minimize the danger of anaphylactic shock. The preliminary subcutaneous injection of the small "trial dose" of serum was recommended. ("Trial dose" was a preferable name to "sensitivity test" or "desensitizing dose," especially as, desensitization was probably impossible in practice.) Trial doses were meant to be absorbed slowly into the general circulation, so that general reaction to a small amount of serum was first tried. If shock should develop, it would probably be mild and readily respond to treatment.

If a patient had not had serum before and had not suffered from asthma or infantile eczema, the main dose could be given intramuscularly; but he *must* be kept under observation for 30 minutes. If, however, there was a history of having had serum previously, the main dose should be preceded by a trial dose of 0.2 ml. subcutaneously. If after 30 minutes there were no general symptoms the main dose might be given intramuscularly. Everything should be at hand for emergency treatment. If there was a history of asthma or infantile eczema the trial dose should be reduced to 0.2 ml. of a 1:10 dilution subcutaneously, followed after 30 minutes (if there were no general symptoms) by 0.2 ml. of the undiluted serum intramuscularly; after another 30 minutes the main dose could follow intramuscularly. In acute cases in which intravenous injection was indicated all preparations for treating shock should be made beforehand. This route should not be used unless a preliminary intramuscular injection had been tolerated.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Mercury in Paediatrics

SIR,—I was much interested in the article by Miss Vera K. Wilson and Drs. M. L. Thomson and A. Holzel on mercury as a possible cause of nephrosis in children (February 16, p. 358), and would like to congratulate them on a nice piece of investigation. I am, however, a little disappointed in the hesitant phraseology of your annotation on the subject (p. 370), which states:

It is important that we should not be driven from our pharmacopoeia through fear. The immediate need is not to jettison useful drugs but rather periodically to review therapy in use and be sure that the value justifies the risk.

This is fair comment only if we are considering useful drugs, and that question does not seem to have been seriously examined. In 31 years of medical practice with adults I cannot remember having once prescribed, or advised the use of, calomel. This may, of course, be due to my ignorance of its virtues, though I prefer to believe that it is due to the enlightened teaching of A. E. Barnes and Edward Mellanby in Sheffield, who gave me, in 1920, a healthy contempt for most of the pharmacopoeia of that day.

Will someone tell me, in 1952, what is the value of calomel in paediatrics? Or is its use, as I suspect, perpetuated solely on a basis of personal preference, custom, and tradition, and on unsupported statements such as those of Bunthorne (R. Bunthorne, see W. S. Gilbert, *Patience*, Act I, London, 1881)?—I am, etc.,

Manchester.

ROBERT PLATT.

SIR,—Your contributors, Miss Vera K. Wilson and Drs. M. L. Thomson and A. Holzel (February 16, p. 358), are to be congratulated on their article drawing attention to the dangers of indiscriminate mercurial medication. Perhaps the moral of their article needs no pointing. Yet it seems to me a pity that the author of your annotation (p. 370) should concern himself with the place of mercurial preparations in the pharmacopoeia.

My experience in infant welfare clinics suggests that mercury is most often given without reference to medical advice. Parents, distressed by the sufferings of teething infants, resort to proprietary teething powders. Time and again mothers, informed that the powder in question is a mercurial purgative, express astonishment and incredulity. It is only natural that the exhausted infant's sleep should be attributed to non-existent virtues of the powder. The need for public enlightenment on this point leads me to comment on the lost opportunity. In the history of Case 5 (p. 359), a 19-months infant who died as a result of taking teething powders, occurs the statement that "permission for necropsy was refused." Does this mean that the coroner failed to order a necropsy? It is a pity he did not hold a public inquiry into the cause of death.—I am, etc.,

St. Peter's-in-Thanet, Kent.

BRIAN WEBBER.

SIR,—Since the publication of our article (February 16, p. 358) we have had the following case under our care.

A boy aged 6 months was admitted to hospital on January 7, with a history of oedema for one week and much albumin was found in the urine. One teething powder containing approximately 0.64 g. (42 mg.) Hg had been given daily for two weeks. The urine contained 175 µg. Hg per 100 ml. A ten-day course of dimercaprol was given. From the sixth to the ninth day the child's weight fell by 2½ lb. (1.1 kg.) and three days later no oedema could be detected. The albumin in the urine decreased rapidly after the sixth day of treatment and a week later had disappeared. The mercury content had fallen to 16 µg. per 100 ml. The apathy which had been present since admission gradually

diminished and there was marked improvement in the child's general condition. So far as we could tell from the mother no other mercury-containing preparation had been given.

What Doctors Prescribe

SIR,—The article on 17,301 prescriptions (February 9, p. 292) by Professor D. M. Dunlop and others is obviously most important to the Government as well as general practitioners. It is also most illuminating, but as it contains one or two misstatements and others which are debatable I should like to make a few comments.

The first is that as there is no Form E.C.10A in England all the suppositions based on its existence are fallacious. I wish this form was allowed in England as well as in Scotland, for it would help our work greatly. The second statement I would contest is (p. 295) "that there are few occasions in practical therapeutics which demand the prescription of more than one drug, etc." This implies that suitable single drugs exist for most clinical conditions (apart from taste, which requires the flavouring), and I think that few practising physicians believe this, not even of adrenaline in asthma. Most drugs have undesirable side reactions, and many of these can be minimized by a careful prescription including adjuvants and correctives. Often the same result can be achieved by prescribing smaller amounts of several drugs which have one action in common, but each with its own different series of unwanted effects. This is, in fact, the principle on which many so-called elegant preparations are based. The authors state that these "must generally be classed as placebos," but the general practitioner, who seems to see a different type of patient than that in hospital or academic practice, knows that some, at least, of these preparations are very valuable indeed. It is mostly in the long chronic conditions that they prove of value, and they often have to be given for a considerable time before they prove their worth. Hospitals are not the places where such patients go; they are the cast-offs of the consultant, or if they attend out-patients the physician in charge has not the time to listen to their manifold complaints and to watch their slow return to health, or the junior medical officers have not the experience to deal with them, or indeed much sympathy either with cases that do not correspond with the types of illness he has been taught to class as "disease."

It is for these reasons probably that the authors speak rather disparagingly of the vitamin preparations and (apparently) of plasters with folic acid. I am constantly surprised, and pleased, at the number of women who tell me that the latter have made life entirely different for them when simple ferrous sulphate had had no effect, and their changed attitude to life shows that they are telling the truth. Other vitamin-B-complex preparations have a similar effect on a different type of woman, and, as my wife has been taking a preparation containing "taka-diastase," aneurin hydrochloride, nicotinamide, and ascorbic acid regularly for over a year, I have had a great opportunity to observe its beneficial effects, though when I first read about it I was nearly as sceptical as Professor Dunlop and his colleagues. The fact seems to be that we still have a good deal to learn about vitamins, and probably about nutrition also, and that besides the various enzyme reactions which have now been discovered for most of them there are probably others due to massive doses (particularly perhaps the fat-soluble A, D, and E) or long-continued smaller doses which cannot be demonstrated on experimental animals but which can be observed in human beings if one has the patience to look for them. After all, science is based on observation, and alcohol can make people merry as well as drunk.

It would be nice to comment on many other points, but I should like to stress the point made about the value of chloral, particularly in children's diseases, though my father—with much longer experience than I have had—preferred bromide except in confinements. The large number of sedatives prescribed can to some extent be justified, not because we are most of us neurotic, but because some doctors are still old-fashioned enough

to believe in the *vis medicatrix naturae*; and certainly many cases (some obscure and some less so) prove that Nature can make a good recovery if once the patient's mind and body are put at rest—which is far from saying that their ailments were necessarily psychogenic. This does not excuse slovenly examinations and diagnosis, but a harassed doctor can hardly be blamed if at times he prescribes a barbiturate which at the worst will seldom do harm and will at least give his patient (and his or her household) a good night's sleep and a better chance of recovery.

After offering these criticisms it is a pleasure to say again how stimulating I found the article and how completely I agree with many of the points raised, and especially the conclusions about the teaching of pharmacology, though I think that 10 or 15 years' experience in general practice might be useful for the teachers, as it certainly will be for their students. But the most important thing is that these latter should be taught to observe the effect of what they prescribe and not simply try to memorize and look for what they have been taught to expect.—I am, etc.,

Winsford, Cheshire.

W. N. LEAK.

SIR,—One statement in the interesting survey of prescriptions on Form E.C.10 (February 9, p. 292), relating to the incidence of pernicious anaemia and diabetes mellitus, does not seem in accord with conditions in this semi-rural area of Lincolnshire. The authors state, "Diabetes is a common disease, while the megaloblastic anaemias are comparatively rare." In the practice in which I am a partner there are at present 23 cases of diabetes on insulin treatment, one on diet only, and two presumptive cases under investigation, a total of 26 cases. Pernicious anaemia cases, in all of whom the diagnosis has been adequately established, number 16. Incidentally, no member of the partnership prescribes liver other than for cases of megaloblastic anaemia. These figures certainly do not seem to justify the comparative labels of "common" for diabetes mellitus and "comparatively rare" for megaloblastic anaemia, at least so far as this area is concerned: If, as is usually claimed, Jews are more susceptible to diabetes, it should be added that there are practically no Jews in south Lincolnshire.

So far as prescribing is concerned, diabetic patients are usually given on one prescription insulin sufficient for about a month, while pernicious anaemia cases receive usually on one prescription enough liver injections to last them for four to six months. In any one month therefore in this practice the average issue of prescriptions is in the ratio of about six insulin prescriptions to one of liver. One imagines that for the convenience of both patient and doctor infrequent prescribing of both insulin and liver is the rule throughout the country. The close relationship in number of the prescriptions analysed by Professor D. M. Dunlop and his colleagues (50 for liver and 68 for insulin) certainly suggests that liver is not uncommonly ordered for disorders other than megaloblastic anaemia.—I am, etc.,

Boston, Lincolnshire.

J. H. F. PANKHURST.

SIR,—A survey of 17,301 prescriptions on Form E.C.10 by Professor D. M. Dunlop and Drs. T. L. Henderson and R. S. Inch (February 9, p. 292) makes some rash statements and draws some rash conclusions. As a G.P. with a mixed practice and a maximum list, I could be one of the 140 or so doctors whose prescriptions have been scrutinized by and subjected to the academic eyes of the authors.

"That 21% of all prescriptions were for proprietary drugs would seem excessive" is politely worded, but carries a sting in its tail. Who are the authors to be able to make such observations? Were they present at the time of the diagnosis, did they see and know the patients, and did they not only follow the cases but also take responsibility for them? Moreover, what do Professor Dunlop and his colleagues mean by proprietary drugs? Are the B.P., and B.P.C., and addenda their criteria? If so, what of such medicaments as the antihistamines, *p*-aminosalicylate, "prisco", vitamin B₁₂, methionine, hexamethonium bromide, and chloramphenicol, which, with many others, may have official names, but may not be in or get into these publications for some time? Are such essential drugs and others that may be patented or are only made by one or two firms to come under the ban? Further,

there are many examples of drugs developed by manufacturers (e.g., "coramine" or nikethamide, procaine penicillin, isoprenaline sulphate, dextroamphetamine, etc.) which are of great worth and only get put into the B.P. and B.P.C. after a lapse of time. Are we, as G.P.s, to be frowned upon for prescribing them for N.H. patients before such drugs are in the official publications?

"Tablets should be prescribed in preference to the corresponding mixture," and, "The powder should generally be prescribed in preference to the mixture." These remarks appear to show little knowledge of and sympathy for the G.P. Such statements savour of the clinic, or of the laboratory with pithed frogs, decerebrate cats, and heart-lung preparations: they could be made by a dictatorial Ministry of Health. Surely the criterion for the form of a medicament is the patient and what suits him best. Some duodenal ulcer sufferers prefer mixtures of alkalis, others favour powders, and a few like tablets to crunch. Sweeping statements such as the two quoted above show a remote control of the patient and a disregard for reality.

"Chloral hydrate was only very occasionally incorporated," and, "Paraldehyde did not appear in a single prescription." Surely paraldehyde is outmoded and chloral hydrate has many drawbacks.

"The value of expectorants is doubtful." It would be more accurate to say the value of expectorants is controversial. However, probably the best answer would be obtained from chesty patients and those who say they have a tight chest and cannot get up the phlegm. Laboratory experiments on animals or humans in which the volume of expectoration is measured on treatment with a drug or a combination of drugs have their value, but the ease and comfort and quicker recovery of the patient also matter, and I feel I can safely advise the authors to try an expectorant mixture (preferably containing tinct. opii camphor. B.P.) when they get a tight chest, and they will yet bless me for the advice.

"It is surprising that adrenaline is prescribed so infrequently." There are many methods of treating asthma. Injection of adrenaline is generally used when other remedies do not work, and even adrenaline fails at times.

"Multiple-vitamin preparations were often prescribed and are undesirable." There is much faulty nutrition to-day among old-age pensioners and office girls, and such preparations work wonders. Further, after a debilitating illness, post-influenza depression, post-operative debility, and for anorexia, they will get people on their feet and back to work.

To say that it is doubtful if "dextrine" possesses any advantage over amphetamine is to go against clinical findings.

Mersalyl is only one of the organic mercurials used, and it is often necessary to change from one to another to get continuous results—e.g., from mersalyl to, say, "neptal."

The suggestion of the authors that more asthmatics should be taught self-administration of adrenaline is not in my view or experience sound advice, but space will not permit me to give reasons now.—I am, etc.,

Luton.

D. R. SNELGROVE.

SIR,—In their survey of prescribing Professor D. M. Dunlop and Drs. T. L. Henderson and R. S. Inch (February 9, p. 292) have performed a useful service, but their suggested remedies seem to us to result from much too blinkered a view. It is clear from their figures that over one-half, and probably as much as three-quarters, of the prescriptions given by general practitioners are for placebos. This is not because practitioners are ignorant of the fact that many of these preparations are pharmacologically inert but because the prescribing of these is apparently the usual, and sometimes the only known, method of dealing with functional illness. The patient is not being treated for the illness from which he is suffering, but is merely being fobbed off.

We have previously (*Lancet*, 1951, 1, 1226) expressed the view that functional illness is the greatest clinical problem facing the general practitioner of to-day. We also believe that, given a correct approach to the psychological and social origins of functional illness, and given adequate time, the general practitioner is well able to deal with the problem. Indeed, with his intimate knowledge of the patient's environment, he is the ideal person to do so.

But a correct approach to the problem of functional illness on the part of the general practitioner implies a reorientation of the selection and training of the student and adequate time for the doctor. The latter can be obtained only with a

reorganization of the general practitioner's conditions of work based on the elimination of economic competition between doctors and the development of group practice at properly equipped health centres.—We are, etc.,

L. M. FRANKLIN. R. TEPPER.
St. Paul's Cray, Kent. J. D. PAULETT. E. TUCKMAN.

SIR,—A few days ago, while travelling by rail from Liverpool to London, I was privileged to have a retired sea captain as a travelling companion. He mentioned in the course of our conversation that he had recently consulted his doctor, who, as a result, gave him a prescription for a cough mixture. He took this along to the chemist and was given in exchange an 8-oz. bottle which he saw being filled from a huge stock container. A week later, the medicine finished, he decided to save both his own time and that of his doctor by obtaining a repeat of the mixture direct from the chemist, expecting to pay, perhaps, a couple of shillings for it. To his surprise, he was given a small 2-oz. bottle for which he was charged 3s. I think the concluding remark of my companion is sufficient comment by itself—i.e., "That sort of thing does not encourage one to treat the doctors considerably or to use the Health Service economically."—I am, etc.,

London, S.W.1.

I. CRAWFORD JONES.

SIR,—The interesting and helpful article by Professor D. M. Dunlop and Drs. T. L. Henderson and R. S. Inch (February 9, p. 292) prompts me to put forward the views of a general practitioner. It stimulated me to examine the deep ignorance of pharmacology which prevents my attaining the therapeutic wisdom and economy indicated. My one textbook of pharmacology is dated 1921. In addition I have by me and enjoy Professor Dunlop's most practical book on medical treatment. Present-day practice allows me no time to read it systematically and only rare moments to refer to it. Patients visited usually want a prescription they can take immediately to the chemist. In the consulting-room, if I turn to the book and say, "This chap knows far more than I do," the patient loses faith and I face.

Manufacturing chemists are anxious to keep me up-to-date: but I have learned to send away their representatives and to use their circulars for salvage. Any recent knowledge I have gleaned comes from R.S.M. meetings, the *British Medical Journal*, meeting consultants and from their letters. Few consultants, I believe, have Professor Dunlop's profound knowledge of the economics of therapeutics. They tend, naturally enough, to prescribe what they want for the patient and to give little thought to the cost. The general practitioner does not often have the opportunity to take up their time discussing the merits of cheaper equivalents. Consequently I find myself often using the expensive but effective remedies learned from these teachers. (It should be remembered, too, that some of the "equivalents" are not as good as the proprietary substances—e.g., Neb. adren. et atrop. co. is nearly always rejected by asthmatics.) The high incidence of proprietary prescribing in industrial areas might be explained by more patients being sent to hospital and so more consultants' letters recommending proprietary remedies.

The small number of injections, I am afraid, may be due to little time and high cost. The niggardly allowance for injections is very discouraging. Professor Dunlop mentions adrenaline for asthma. I find this short-acting cheap drug is a mere placebo compared to the long-acting ninepenny ampoule of adrenaline in glycerin. Ninepence is our pay for looking after the patient for eighteen days or the injection allowance for 30 patients for a year. I love my patients, but I fear my banker.

Vitamins are an excellent example of prescribing difficulties. In view of the increase in respiratory infections and post-operative haemorrhage some general practitioners doubt the value of *ex cathedra* statements that the post-war diet is adequate for work and for convalescence. We tend, therefore, to prescribe vitamins hopefully. Our prescriptions are

often extravagant because we are confused by consultants' letters and manufacturers' pamphlets, and we do not know whether we shall be treating our patients adequately by telling them to drink more milk and take brewers' yeast. Liver, I think, is grossly over-prescribed as the result of advertising. For my part, I am waiting until I get a case of pernicious anaemia.

Another circular we all suffer from is the *National Formulary*. Professor Dunlop comments on inadequate doses of bromides. Let him look in the *Formulary* to see what guidance we get there.

Cold Vaccines.—On this subject my bow to Professor Dunlop's authority is a purely formal one. In spite of the inconvenience—and, for private patients, expense—my patients keep coming back for anti-catarrh vaccines because both they and I know they work. If one excludes sinus infections and ignores makers' dosage, the results are good. I kept records for two years and found that about 70% benefited at least by having fewer and less severe colds, and many of these had no colds at all.

Mersalyl.—In my case ignorance of pathology and fear of damaging kidneys make me very cautious of using mersalyl without a consultant's advice.

Conclusion.—The general practitioner's handicaps are not indifference, but lack of time, confusion, and lack of knowledge—in which exclusion from hospital practice is a big factor. I have real doubts about whether the teaching of economy in prescribing would be well done by consultants in hospital, and I am sure it is not a bedside subject. Students might get glimpses if and when they are apprenticed to general practitioners.

If time could be found, the general practitioner himself would benefit by being paid to go to postgraduate courses in pharmacology, conducted as seminars by physicians and pharmacologists, with pharmacists and general practitioners as critics. Courses such as these would benefit the patients, make us happier by refreshing our knowledge and self-confidence, and pay for themselves by the resulting economy and efficiency in prescribing.—I am, etc.,

Wembley, Middlesex.

M. C. ANDREWS.

Ryle's Tube in the Trachea

SIR,—On two occasions in the last 18 months I have had the same experience as Mr. Eric Coldrey's anaesthetist (February 16, p. 382) and had to remove a Ryle's tube from the trachea before passing an endotracheal tube. On several occasions I have found the Ryle's tube coiled up in the pharynx and tolerated with no apparent difficulty.

My patients have been aged, dehydrated and acidotic, and perhaps this accounts for the surprising tolerance of the pharynx and larynx. The premedication would add to the tolerance by causing further dehydration and depression of the pharyngeal and laryngeal reflexes.—I am, etc.,

Richmond.

GORDON C. THICK.

SIR,—I was very interested in Mr. Eric Coldrey's letter (February 16, p. 382). Before an emergency laparotomy one evening I requested, after a stomach washout, that a Ryle's tube should be passed and left *in situ*. It was passed without any difficulty. The patient seemed very comfortable, except that he had "a slight tickle" in his throat—nothing more. When about to pass a tube into the trachea, the Ryle's tube was seen lying between the cords.—I am, etc.,

Birmingham.

BETTY THOMAS.

Stellate-ganglion Block

SIR,—I have used the technique mentioned by Dr. J. A. Lee (February 16, p. 381) many times since it was first described by René Leriche and Fontaine (*Pr. méd.*, 1933, 41, 1819), so that the suggestion that Dr. Virginia Agar was the originator of this method is incorrect. Leriche and Fontaine give more detailed directions than does Dr. Lee;

NEW treatment for Parkinsonism

Initial trials of 'Kemadrin', a new compound for the treatment of paralysis agitans, have shown that it causes a decrease of rigidity and leads to better muscle co-ordination. Patients under treatment are able to indulge in greater physical activity and show feelings of increased well-being and alertness. Less paralytic ileus, less constipation, less retention of urine and less mydriasis occur than when large doses of the traditional remedies, the belladonna and stramonium alkaloids, are used for controlling this syndrome.

Further trials are in progress, but the initial results have been considered sufficiently favourable to allow immediate release of 'Kemadrin'. Issued as compressed products of 5 mgm., 'Kemadrin' is available in bottles of 25 and 100. Further information on request to 183-193, Euston Road, London, N.W.1.

'KEMADRIN' BRAND

and there is no doubt that, simple as the procedure is, it does call for a little more knowledge than is contained in his letter.

I hope later to record a number of cases of aural vertigo treated by stellate-ganglion block; but perhaps I may say here that it is often valuable in this distressing complaint, although, surprisingly, it does not appear to have any effect on tinnitus.—I am, etc.,

London, W.1.

A. PINEY.

SIR,—With reference to Professor René Leriche's article (February 2, p. 231), I think it might be of interest if I recalled some of the observations from several hundred procaine stellate blocks and approximately 160 sympathectomies, all of which I have performed for disorders of the internal ear, such as Ménière's disease, tinnitus, and a few selected cases of nerve deafness.

There is no doubt that sympathectomy has an influence on the cerebral circulation if one can regard the internal auditory artery as being a part of the cerebral circulatory system. During the course of a fenestration operation I have seen under the microscope the minute labyrinthine blood vessels dilate as the result of a procaine stellate block. This is recalled in *Proc. roy. Soc. Med.*, 1951, 44, 760. Here, then, is proof that the cerebral circulation is definitely under sympathetic influence.

It is of interest to recount the effects on concurrent conditions in some of these patients who underwent operation (either stellatectomy or upper dorsal sympathectomy).

(1) Nine patients had migraine on the side of the operation: none of them has had any attacks since. The state of mental anxiety, worry, and depression accompanying Ménière's disease was completely lifted in all cases where the operation was performed bilaterally—in fact this is the commonest spontaneous remark of the patients post-operatively, "that they feel a weight has been lifted from them." They no longer have the bursting pressure bands around their heads or the feeling of a weight pressing on the vertex. It would seem that this functional symptom is influenced for the better by the operation.

(2) Eight cases had cardiac palpitations: these also appeared to be relieved.

(3) Three patients had severe occipital cephalgia; and this was relieved also. The patients said that they were able to take an interest in life and concentrate on their work again.

Apart from the effects on disorders of the internal ear the most striking effect appears to be on the higher centres.

I thought that this long series of cases and these few observations might be of general interest.—I am, etc.,

London, W.1.

E. R. GARNETT PASSE.

Vascular Spasm

SIR,—Mr. John Sophian has performed a useful service by pointing out in his letter (February 16, p. 382) that vascular spasm "as the result of nervous intermediation" is not an imaginary occurrence or always a deduction from faulty observation. The nicest demonstration of vascular spasm (and of its relief) is seen in schizophrenic patients whose low metabolic rate may require additional physiological mechanisms for preserving body heat. The brachial vessels below the level of the axillary artery, and the vascular tree of the lower limb below the popliteal artery, are not infrequently affected (*Proc. roy. Soc. Med.*, 1950, 43, 623). The main vessels, however, remain patent except at their terminal arborizations. When the small terminal vessels are occluded there is no bleeding from fingers or toes after pricking, and gangrene may supervene. The main vessels are easily palpated and rolled under the finger; they are very firm and very narrow in calibre, and they are pulseless. The spasm of these vessels is relieved after warming an "indifferent" limb (so-called reflex vasodilatation), and after anaesthetization of the sympathetic vasoconstrictor supply. The condition is also alleviated by a remission, either spontaneous, or following insulin treatment or E.C.T. Prolonged warming of the extremities will usually avert any considerable loss of peripheral parts, although flaking of soft tissues and atrophy of the nails is often observed. The

post-mortem appearance of the vessels of these patients is normal, with the possible exception of hypertrophy of the muscular coat of medium and small arteries.—I am, etc.,

Arlesey, Beds.

F. MACKENZIE SHATTOCK.

Hypnotism in Medicine

SIR,—Hypnotism is a mode of treatment which has an important place in medicine. It cannot be adequately studied or practised in abstraction from wider psychiatric considerations or without training in psychology and in analytical psychotherapy.

Hypnosis is a mental state of increased suggestibility, becoming dangerous when it reaches the deep stage of "hypnotic trance," which I have defined as "a secondary state of mind, produced by definite methods, leaving behind it amnesia or loss of memory for that particular mental state, and at the same time, or alternatively, involving pronounced anaesthesia to painful impressions" (*Brit. med. Bull.*, 1949, 6, 1307). Such a stage of deep hypnosis clearly involves mental dissociation and is not entirely normal.

Persons who are easily hypnotizable are those most susceptible to mental dissociation and are therefore in need of reassociation and mental integration. It is my experience that such persons become less hypnotizable after a course of integrative psychotherapy. In this my experience agrees with that of Pierre Janet, as I discovered in an interview with him when he attended the 7th International Congress of Psychology at Oxford in 1923. Hence one's psychotherapeutic aim should be to obtain beneficial suggestion effects with the minimum of dissociative hypnosis. Increased suggestibility in itself is neither good nor bad, although not free from danger, and can be turned to good effect only through the imposing and repeating of good (health-giving) suggestions. But the full establishment of such improvement and recovery needs supplementation by some form of active psycho-analytical treatment, so that the "transference," or psychological dependence of the patient upon the physician, is resolved, and the patient can then stand on his own feet and complete his cure by autosuggestion, neuromuscular relaxation, and deepened self-knowledge (autognosis).

On the other hand, the beneficial effects of suggestion treatment, especially if repeated for a considerable period of time, in the case of voluntary and autonomic nervous dysfunction and endocrine disturbance, can find a proximate explanation in terms of I. P. Pavlov's theory of conditioned reflexes, and may be regarded as examples of successful *reconditioning of nerve reflexes* and of bodily functions in general. I have myself set this out in my article "Hypnosis, Suggestibility, and Progressive Relaxation," in 1938 (*Brit. J. Psychol.*, 28, 396), while indicating that this theory cannot explain *all* the phenomena of hypnosis—e.g., the recall of lost memories in a moment of time under hypnotism, etc.

But, of course, the practice of hypnotism (deep or light) in medicine should take full account of the underlying mental causes of illness as well as of physical and mental symptoms, and should therefore be accompanied by adequate mental analysis and mental and physical rehabilitation.

Looking back on nearly 40 years of experience of medical psychotherapy, I feel inclined to declare that hypnotism is a method to be overpassed wherever possible, and that the watchword of modern psychotherapy should be "Beyond hypnotism."—I am, etc.,

London, W.1.

WILLIAM BROWN.

SIR,—May I comment upon the reply given in "Any Questions?" (January 19, p. 173) to the query concerning the place of hypnotherapy in chronic asthma, and at the same time offer some criticism of the attitude generally adopted to this procedure by the journals of the B.M.A.?

Hypnotic treatment can, in my experience, frequently be of the greatest benefit to sufferers from chronic asthma, and indeed from other psychosomatic disorders. Moreover, in a considerable experience of treating children by this method I have never seen any undesirable side-effects, and I doubt if many medically qualified users of the hypnotic method have seen them either in their own patients. Nor can I even visualize the possible occurrence of any adverse manifestations so gross as those described in the answer to your correspondent while treatment is in the hands of a medical hypnotist, and this for the very good reason that none of those symptoms could possibly arise spontaneously, but

would have to be induced either deliberately or from utter incompetence on the part of the hypnotist. Generalizations concerning the occurrence or frequency of such after-effects savour rather of experience derived mainly from the results of stage exponents of hypnotism and the sensational articles of the Sunday newspapers.

Surely it is time that the official journals of the B.M.A. approached the subject of medical hypnosis with the honesty and impartiality that one would expect of a scientific body, and stopped the present practice of making it possible to criticize and dogmatize on this particular form of therapy, under the cloak of anonymity, by persons who may or may not have had first-hand experience of hypnotic procedure. In the January issue of *Family Doctor* the only unsigned article, apart from the editorial, dealt with hypnotism, while every other contribution appeared under the name of its author, whose status and integrity were thereby vouched for. The unknown writer of this paper concluded by saying, "It (hypnotism) is still an art and it depends so much on the individual hypnotist that the type of controlled survey and experiment which would make it scientifically acceptable and measurable is still a long way off. It will reach that phase one day, and at that point hypnotism will fall into line with other branches of medical science." As the end-piece to a recital of various difficulties maybe associated with the technique it is quite apparent what impression the anonymous author seeks to create; but the first part of the statement quoted would, as it stands, be equally applicable to the assessment of any surgical procedure which is also an art and where so much depends on the individual operator, though the procedure may be none the less generally accepted for all that. The second part of the quotation is, of course, deliberately misleading in that it sets out to suggest to the lay reader that only the sciences have any accepted place in the practice of medicine. This we doctors know to be quite untrue, for though use may be made of many sciences the practice of clinical medicine as a whole is still an art. Nor is there any reason why a controlled survey of the results of treatment by hypnosis of suitable cases of a particular disease should not be compared with those obtained by other methods, it being understood, of course, that both would be carried out by medically qualified persons. If this is the sort of exposition and assessment that is put out for consumption by the lay public in an official organ of the B.M.A. it is small wonder that the public is driven to quacks, charlatans, stage performers, and writers of sensational articles in the press for information on an important medical topic. If this article and the reply in "Any Questions?" are examples of the only sort of thing that the medical profession has to say on a subject of this kind it is not surprising that little or no notice should be taken of us as a profession when we condemn the use and abuse of hypnotism by unqualified persons, or seek support to have exhibitions of it banned by law from stage and screen. Until the subject is thrown open to unbiased examination, criticism, and discussion in our own journals, until we are prepared to approach the subject in a purely objective manner and with the scientific detachment that might properly be expected of us, instead of merely reiterating opinions apparently based on the vast quantities of sensational rubbish published by unqualified persons, we have no right as a profession to assume any particular attitude or claim any particular authority in respect of this still neglected subject. To anyone seeking medical assessment of an orthopaedic procedure, for example, we would offer only a reasoned opinion based solely on the experiences of qualified surgeons skilled in the technique and not on those of the bone-setter; to a question concerning the evaluation of the place of morphine in the practice of medicine we would not confine our remarks to a statement stressing the dangers of the drug, its capacity for causing addiction, and to describing the results thereof, or base our evaluation on the results of its mishandling by dope pedlars or its abuse in the opium den. We have a responsibility in this subject of hypnosis and its place in the treatment of disease; it is therefore up to us to clear our minds of past prejudices and to see that we are thoroughly enlightened and informed on the matter before we presume to try to influence others.

—I am, etc.,

Woodford Wells, Essex.

JAMES A. O'CONNOR.

SIR,—With reference to Dr. Gordon Ambrose's letter concerning hypnosis (February 9, p. 326); there is no need for medical men to rely on the popular press and stage or lay hypnotists for information on this subject. The British Society of Medical Hypnotists (all fully qualified medical men in this country), which includes the majority of the world's recognized authorities on this subject (authors of

textbooks, etc.), has trained medical men and arranged lectures to universities, B.M.A. Divisions, etc. The Society publishes a quarterly journal (*The British Journal of Medical Hypnotism*), now in its third volume, and has produced instructional films. It has been consulted by Members of Parliament and the Ministry of Health for expert advice concerning the banning of stage hypnotism.

Hypnotherapy is probably the only effective treatment in many nervous and allied cases—asthma, alcoholism, etc.—but it is important to draw a sharp distinction between medical hypnotism and the stage variety.—I am, etc.,

London, W.1.

S. VAN PELT.

SIR,—I am reminded by your correspondence under this heading that as long ago as December, 1913, at the Leeds and West Riding Medico-Chirurgical Society I showed a case of bronchial asthma associated with pregnancy and treated by hypnotic suggestion.

My notes made at the time record that the patient was a married woman, aged 25, who had suffered from bronchitis since childhood, and for the last two years from recurrent attacks of typical bronchial asthma, increasing in frequency and severity until latterly they occurred once a week or more often still. Her health was much disturbed in consequence. There was almost constant dyspnoea between the attacks. She was unable to walk out alone, and unable to assume the recumbent posture at night. The patient was first seen in July last—i.e., 1913—during a typical attack. She was then six months pregnant, looked very ill, and was suffering from chronic laryngitis. Treatment by suggestion began immediately after. Sitzings were given three times a week to begin with, later once a week. She proved readily susceptible to hypnosis at the first sitting. At the second sitting there was complete muscular relaxation and amnesia during "sleep." On subsequent occasions post-hypnotic suggestions were readily carried out, and the patient conversed without subsequent recollection. Suggestions were given that the attacks would be less violent and less frequent and eventually would cease. Complete cessation of the attacks was insisted upon as the treatment advanced. The result was that the patient had been free from asthma up to the time of the record. Her household duties had been resumed, and she was able to lie down flat at night—almost an unprecedented occurrence. The huskiness of the voice did not subside until after some nine weeks of treatment. Labour occurred at term without complication.

I have never seen any untoward results from therapeutic hypnosis, and fully agree with your correspondent, Dr. A. P. Magonet (February 9, p. 326), that "in time this will be the method of choice in the treatment of this psychosomatic symptom." Equally do I agree with your correspondent, Dr. Gordon Ambrose (February 9, p. 326), in his view that it is high time that hypnosis as a therapeutic agency should be placed once and for all under the aegis of those who have made a special study of the subject, and above all whose professional probity is above question. I am relieved to hear (*vide* Dr. Ambrose) that therapeutic hypnosis is now regarded as respectable but harmless. What a time it has, so to speak, achieved an official imprimatur, we may hope to see evidence of a more enlightened attitude on the subject.—I am, etc.,

Leeds.

J. E. MIDDLEMISS.

Xylocaine

SIR,—The letter from Dr. P. R. Bromage on "xylocaine" (February 9, p. 328) attracted my attention, as I have recently completed notes on a small series of 200 dental cases. In this, details were kept about time of onset of analgesia for various amounts and positions, duration, side-effects, etc., using a 2% solution with adrenaline 1 in 80,000 (awaiting publication).

Dental work is particularly suitable for comparison of a new local analgesic with other agents because of the variety of work, from conservative to minor surgical, which can be done; and also because nerve blocks and local infiltration for opposite sides can be compared conveniently using different analgesics.

In this series a small number of procaine controls were observed in similar circumstances, and there is not the least doubt in my mind that xylocaine is superior in every way to procaine and, from my experience, to any other local analgesic which has been made available for dental work. Side-effects are minimal, onset of analgesia is more rapid and duration longer, while much smaller doses—as little as half or less of the usual procaine dose—are equally or more effective. Furthermore there appears to be less motor involvement seen in the lip in anterior injections, particularly when small doses are used—a source of annoyance especially to women patients. A further 2,000 injections carried out since the original notes were made have only served to confirm my original impression.

I have no experience of epidural block, so that naturally direct comparison of observations with Dr. Bromage is not possible, but, while I feel that his contention that "rapidity of action might be confused with greater certainty of effect" is a reasonable one, yet I believe that he is mistaken and that *both* these attributes are evident in xylocaine analgesia.—I am, etc.,

Dublin.

ADRIAN COWAN.

SIR,—May I, as the responsible surgeon, add some details to your medico-legal report (February 2, p. 280) on the death of a patient following the use of xylocaine as a local analgesic? It is important that there should be the clearest understanding and that unfair blame should not fall on this valuable analgesic agent.

Most of the facts are given, correctly, in your report. The strength of the solution used was 0.8% and the total amount of the drug not more than 0.64 g. No adrenaline was used in the solution. No drug was given as pre-operative medication. The weight of the patient was 7 st. 13 lb. (50.3 kg.), and the time taken for the injection about 15 minutes.

This patient had had previous injections of xylocaine, probably amounting to about 100 ml. 0.5% solution with 1/200,000 adrenaline, combined with a general anaesthetic, for one or more of the stages of the thoracoplasty without any unusual reaction being manifest. She was also previously well known for her liability to "faint" on the occasion of minor surgical interference.

It is my belief, in general, that the more serious of these abnormal reactions during the injection of local analgesics are attributable to overdosage unless there is very good reason to the contrary. The overdosage is often not in the total amount of the drug used, but in too much of it having reached the wrong place, presumably the brain, in too short a time. Thus too rapid absorption from normal tissues or absorption by abnormal routes, and the concentration of the solution used, become possible factors concerned in the effect.

We have no reason to suspect intravascular or intrathecal injection, the plunger of the syringe being withdrawn repeatedly during each injection without revealing blood, C.S.F., or air. Dr. Heggie, who performed the post-mortem examination, expressed the opinion that an unusual amount might have been absorbed from the extensive area of granulations around the organizing blood in the Semb's space and the wound.

An additional factor remains in not having used adrenaline in the solution. This would certainly have delayed absorption from normal tissues.—I am, etc.,

Oxford.

CLEMENT GRIMSHAW.

SIR,—While I find myself in agreement with most of the statements in Dr. P. R. Bromage's letter on xylocaine in epidural block (February 9, p. 328), there are one or two points in which my experience runs counter to his. I believe that xylocaine *does* have a more certain action than other local analgesics. I have never had a complete failure with xylocaine, but have had more than one with "nupercaine" and "amethocaine." Also partial failures are three times as common when these latter drugs are employed.

As an example, a certain patient had to have two caesarean sections at an interval of two years, the first with nupercaine and the second with xylocaine, exactly the same technique

being used on each occasion. With nupercaine she was uncomfortable and had to be given "evipan" after the birth of the baby—with xylocaine she felt nothing, and has indeed described her experience in another journal.

The infrequency of partial failures with xylocaine may be explained by the extraordinary spread of the drug in certain cases. To cite another example, for a perineal operation a patient was given 25 ml. xylocaine between L 4 and L 5, in the sitting-up position. The resultant analgesia, although it spread to the coccyx as expected, also spread upwards as high as T 9. It would, I think, be inadvisable to give xylocaine in a continuous caudal block to relieve the pains of labour, as analgesia would almost certainly extend above T 10 and affect the motor nerve supply of the uterus.

I agree that the 2% solution is too strong, and habitually use a solution of 1.5%, but with this strength I find that analgesia cannot be guaranteed for longer than one and three-quarter hours. If, however, a Tuohy needle and indwelling catheter are employed this is of small moment. Another curious property of xylocaine is the drowsiness which it induces. When using amethocaine for regional analgesia for thoracoplasty it is frequently necessary to calm the patient with light chloroform anaesthesia. With xylocaine, on the other hand, they nearly always go off to sleep. This may well be due to the more certain action of xylocaine.—I am, etc.,

London, W.1.

MASSEY DAWKINS.

Medical Aspects of Road Safety

SIR,—All neurologists see an alarming number of epileptics who drive cars regularly. These persons perjure themselves when they apply for a driving licence, and even persuade themselves either that they know when a fit is likely to occur or that they have not got "real epilepsy." The function of a doctor is not to inform against his patient, and the only remedy is a stricter physical examination before a licence is issued, or the enforcement of severe penalties against unfit drivers.

In this category of unfit drivers, I have seen in the last few years persons driving cars with severe paralytic disease of the legs and arms, entirely inadequate vision with bilateral cataracts, and advanced cardiac disease. It is noteworthy that the patient in every case considers himself entirely fit to drive and refuses to admit that he could not do so, and it is strange how often quite reasonable people become entirely unreasonable if their fitness to drive is in any way questioned. They never will admit that at any time their physical unfitness may be responsible for the death of an innocent person.

In a large hospital at least 60% of all motor accidents admitted during the evening and over the weekend have involved drivers who have taken alcohol, and, whilst many of these drivers could not in any way be said to be drunk in the accepted sense of the term, their reaction time has been sufficiently impaired and delayed to make them unfit to drive a motor vehicle. We in this country have entirely neglected the problem of the alcoholic driver, and the only solution which seems at all practicable is the adoption of the Scandinavian method of prosecution if the driver of a motor vehicle is found to have a blood alcohol of over a certain figure. The adoption of this measure in Sweden has greatly diminished road accidents. It is interesting to see in Sweden how carefully this law is respected and how, in a couple attending a cocktail party, either the husband or the wife will take only soft drinks.

At times this law may appear to be unfair, as recently was shown in the case of a Swedish surgeon who was convicted although his raised blood alcohol was found at least 12 hours after any consumption of alcohol and was due presumably to a slow absorption from the stomach. This may seem unduly hard on the motorist. Persons in charge of other vehicles should also be physically fit, and if an alcoholic pedestrian is responsible for an accident the same penalties should be applied.—I am, etc.,

Bristol.

A. M. G. CAMPBELL.

School Medical Service

SIR,—Your commentary (January 26, p. 210), conclusions, and great disappointment that the number of children found verminous at school is falling so slowly just show how misleading statistics can be. Statistics compiled from the reports of school medical officers, which are compiled from the figures given by the nurses who make the inspections, whose findings depend on the frequency and accuracy of their inspections and the standard they adopt, cannot be regarded as even approximately correct so long as the factors on which they are based vary so widely as they do at present and when compared with the past.

The standard alone can play havoc with any statistics unless the same standard is used by all. Within the past 15 years the definition of what constitutes a verminous head has varied from heavily infested to the one nit standard now recommended by the Ministry of Education. But how many work to this standard is anybody's guess, and how many who say they do spend enough time to make sure that they do is also anybody's guess. The results of Dr. Mellanby's investigation into the incidence of head lice in 1940 when he found 50% or more of schoolgirls' heads were infested, and of a further investigation in 1947 which showed over 41% infestation in girls aged 9 to 13 in cities, compared with the mere 8% mentioned by the chief medical officer in his report on the health of schoolchildren for the years 1948 and 1949, illustrate very well the difference in results obtained when all the factors are comparable and when they are not, and how erroneous it is to draw conclusions from the latter.

However, I can assure you from my own experience as a school medical officer that the position now is much better than 15 years ago and than it appears to be statistically, because heavily infested heads are to-day as rare as they were common in the past. I think all my colleagues who can look back 15 years or more will agree with that. Even if the statistics mentioned by the chief medical officer are correct, which I beg leave to doubt for the reasons already given, they are not comparable with statistics of 15 years ago, when only really verminous heads were classed as verminous, whereas those with a few nits, much less one nit, were unmentioned or completely overlooked. As Dr. Joad would say, it all depends what you mean by verminous.

Your final recommendation that local authorities should combine to attack infestation at its source received scant support from the powers that be when they cancelled the Scabies Order (1941) with almost indecent haste, and so deprived local authorities of the power to follow up infestation to its source.—I am, etc.,

Gosport.

G. W. FLEMING.

Attempted Suicide

SIR,—One cannot but admire the humanity of the approach to the question on attempted suicide ("Any Questions?" February 9, p. 339). However, though the question primarily concerned general practice, I feel the answer should be amplified lest junior hospital residents should be lulled into a sense of false security. Recently a hospital medical officer was severely criticized by a coroner for not reporting such a case to the police, since there were suspicions of foul play. A hospital medical officer does not often know the full facts and, in my opinion, is most unwise not to report these cases.

Another problem which I always found difficult was that of watching these people. When least expected an attempted-suicide patient may make a further attempt. To-day hospitals certainly have not sufficient nurses to watch these patients day and night. In the event of a second attempt being successful, the hospital resident may hear some harsh words from the coroner, particularly if the first attempt was not reported to the police.

Therefore I urge hospital residents to cover themselves by immediately shifting the onus of watching these people on to the family or the police. The most satisfactory solution, however, is to get the patient moved to a mental hospital for specialized treatment as soon as immediate treatment of the poisoning or injury has been successful.—I am, etc.,

London, N.4.

PHILIP JACOBS

Lysivane in Parkinsonism

SIR,—On reading the article by Dr. Hugh G. Garland on parkinsonism (January 19, p. 153) I was very interested in the reference to pain and discomfort in the joints and muscles.

I have recently treated a woman aged 74, who has had the disease for some years and been bedridden for the last ten months. All the characteristic signs and symptoms were present, notably severe pain and stiffness in the shoulder-joints and pain in the epigastrium. No cause could be found to account for these, other than that they were part of the syndrome.

Treatment had been given with the usual drugs, belladonna, stramonium, etc., with no improvement. Four months ago she was put on "lysivane," four tablets daily. Improvement was apparent immediately, most marked being the disappearance of pain both in the shoulder-joints and epigastrium. Within a reasonable time the joints were mobile. The patient has progressed remarkably and can now move about the house unaided.

No other treatment has been given during the past four months, and no toxic effects noted from the drug.—I am, etc.,

Leicester.

ERIC LODGE.

Iridectomy in Congestive Glaucoma

SIR,—It was a pleasure to read Mr. John Foster's masterly survey of the common causes of curable blindness (February 9, p. 318). I do not, however, share his optimism concerning the result of iridectomy in congestive glaucoma. 90% of cases may well be cured of increased tension, but the visual results are the most dismal in ophthalmology, and depend upon the duration of the acute attack more than upon any particular type of operation.

In regard to cataract, Mr. Foster states, *inter alia*, that if care is exercised in not reading when the eyes are tired the changes in vision are usually slow. I do not think we are really justified in restricting our patients' visual activities in this way, and I shall be glad to know if Mr. Foster has any arguments in support of his statement. May I be allowed to qualify Mr. Foster's remark that "cataract extraction is performed under local analgesia"? Thanks to the introduction of thiopentone, and the co-operation of Professor Macintosh and his staff, it has been possible at Oxford to introduce general anaesthesia for all cases where such an anaesthetic may safely be used. Most general surgeons appreciate the comforts of general anaesthesia, and I do not think it will be long before ophthalmic surgeons follow their example in cataract surgery.—I am, etc.,

Oxford.

VICTOR PURVIS.

Peckham Health Centre

SIR,—I notice that in your annotation on family research at Peckham (February 9, p. 317) you state that the L.C.C. will "keep in being what has been described as the only experimental station where mankind can pursue one aspect of his proper study—man in his environment."

With the good will of the Ministry of Health and the L.C.C., we—the originators of the experiment—could have had financial backing from the same sources as they are now about to tap. Their blessing and approval were denied to us. True, at one period in their consideration of our proposals before the war, they offered us financial help—but "on conditions." In the face of their disapproval we could do nothing to gain the necessary financial help from the various foundations, capable and in some cases willing to give it. Scientific experiment cannot be carried on "on conditions." Any experiment must dictate its own conditions.

Our previous experiments had led us to the hypothesis that the human organism was the home with its family nucleus and that this was so in virtue of Nature's tendency to wholeness, health, and healing. General practice was founded and practised in the home with its nucleus, the family. From time immemorial medical art and science have rested on Nature's tendency to wholeness and health, and, indeed, though both have deserted the home both still trade on that natural tendency. It is well recognized that the success of the physical sciences, as distinct from all biological branches of science, rests on the other and antithetic tendency in Nature—the natural tendency to a maximum, or

gratifying relief

'Pyridium', taken by mouth, produces local analgesia of the urogenital mucous membrane, often within twenty minutes of the first dose. This is due to direct action on the mucosa, and there is no systemic sedation or narcosis.

'Pyridium' is indicated for the relief of such symptoms as painful or scalding micturition, frequency, urgency, and strangury.

In therapeutic dosage, two tablets t.i.d.

for an adult, 'Pyridium' is non-toxic and offers gratifying relief in most cases of irritation or infection of the urogenital tract.

'PYRIDIUM' tablets

allness—i.e., the entropy principle of Clausius. I am often tempted to speak of the natural tendency to wholeness and health as the *eutropy* principle, on which the science of hygiene has still to be founded.

We have cleared the ground already—collected the material suitable for study and developed new techniques. Now the L.C.C. has commandeered the site to meet a dire emergency in the disease of the nation. (In this connexion see Dr. Ffrangcon Roberts (February 9, p. 321).) Nevertheless the authorities, having stifled this work at Peckham, still seek to acquire its prestige.

One feature of the Peckham technique will have been carefully noted by the B.M.A. After every cure (either in hospital or by the general practitioner) the discharged patients submitted themselves as a routine for a health reassessment. In other words, not by design but by necessity we have become a sort of censor to medical efficiency in all branches of therapy. Could that be one of the objectives the authorities have in view? Has every therapy now to have its official censor? I would insist that the Family Club at Peckham was an experiment; it was not, as some of my medical critics assume, a borstal institution for delinquent parents. In this Peckham experiment we have reproduced the conditions of the village green across which the general practitioner continually moved through the life of the village. We shall rest content if through our experiment, truncated though it is, we have focused attention on the home with its nucleus, the family, and spotlighted the primary principle, Nature's own tendency to wholeness, health, and healing.—I am, etc.,

Rotherfield, Sussex.

G. SCOTT WILLIAMSON.

Malignant Granuloma of the Nose

SIR,—I would like to comment on the interesting paper by Drs. I. B. Sneddon and J. Colquhoun entitled "Granulomatous Ulcer of the Nose Treated with Chloramphenicol" (February 9, p. 298).

This disease is commonly known, owing to its usually fatal outcome, as "malignant granuloma of the nose." Williams (1949) suggested calling it "lethal granulomatous ulceration involving the midline facial tissues." A successfully treated case therefore merits hopeful attention.

The aetiology and pathology of the condition are obscure. Antecedent chronic infection and bacterial hypersensitivity are factors certainly to be considered. The authors have presented therapeutic evidence for the bacterial origin of the condition of their patient. The lack of histological evidence will, however, make it more difficult to correlate their findings with those in other cases of malignant granuloma of the nose with a similar bacteriology.

We have described a patient with the peculiar association of "malignant" giant cell granuloma of the nose and polyarteritis nodosa (Howells and Friedmann, 1950). Cultures from the maxillary antrum showed, as in the authors' case, a mixed growth of *Streptococcus beta-haemolyticus*, penicillin-sensitive, and *Staphylococcus pyogenes*, sensitive at first to penicillin. After intensive treatment with 16 mega-units penicillin only *Staphylococcus pyogenes*, now penicillin-resistant, could be grown. The patient died of uraemia, and this organism was also grown from post-mortem specimens from the sinuses and spleen. We have suggested that the granulomata in the nose could be a local manifestation of the generalized vascular disease, due to hypersensitivity to an unknown bacterial or chemical agent.

This association of granulomatous lesions in various organs with polyarteritis nodosa has been frequently noted (Lindsay *et al.*, 1944; Weinberg, 1946). Other authors, and otorhinolaryngologists in particular, have focused their attention almost entirely on the local lesions in the nose and sinuses. Only in two of the ten cases referred to by Stewart (1933) was there a necropsy performed, apparently without further microscopical examination of the organs. On the other hand, many pathological reports on polyarteritis nodosa have not mentioned the histology of the nose and upper respiratory tract, though not infrequently there has been a history of long-standing infection of the upper respiratory tract in these cases. The relationship of the peculiar granulomata to the vascular lesions is difficult to explain. Hypersensitivity due to chronic infection may be the underlying cause leading to the terminal development of polyarteritis nodosa. In some patients, however, the granulomatous lesions in the nose and sinuses may possibly represent a local manifestation of the vascular disease itself. The author's case apparently does not belong to this group of malignant granuloma of the nose.

That polyarteritis nodosa does not develop in every patient was shown, for example, by the interesting case of lethal granulomatous ulceration of unknown aetiology of the upper respiratory tract presented by Stansfeld at the meeting of the Pathological Society in Cambridge, January, 1952.

Malaria

SIR,—The treatment of malaria by intramuscular injection of quinine has been discussed recently in your columns by correspondents of considerable experience and repute. The debate on this point has been resumed as regularly and as inconclusively as the wall game of a noted school. It is difficult to avoid inferring that here is a question for which there is no nicely calculated yes or no.

It is certain that in therapeutic effects quinine is less successful than the newer preparations in use in eradicating all forms of the malaria parasite. Quinine is, secondly, a drug with unpleasant side-effects, and on intravenous administration its direct access to the tissues results in cytotoxicity unless it is well diluted. That cytotoxicity amounting to macroscopic necrosis may occur after intramuscular injection has, in the third place, been widely recognized for a long time.

So let us review the circumstances under which its proponents use the injection intramuscularly. The patient in the average instance is distressed and complains of profound malaise and nausea; oral feeds are not retained in amounts adequate for tissue needs; sweating is profuse and there is considerable weakness. Even if the physician is not beset with the care of many other cases, nor by the pleading of the patient's family, he cannot ignore the fact that this is a medical emergency which has potential dangers.

At this point the administration by various routes of mepacrine, proguanil, and similar preparations has often had complete success. The use of intramuscular injection of quinine at this point nevertheless produces in most cases (as ex-patients, such as Dr. H. G. Caldwell (November 24, 1951, p. 1280) and myself, can attest) a far more rapid improvement and removes the possibility of a serious outcome. But, realizing that this is strongly disputed by the anti-cinchonists, I would like to say that it has been very reassuring to see the clear statement on this by both Sir Gordon Covell (October 27, 1951, p. 1021) and Sir Philip Manson-Bahr (December 8, 1951, p. 1403).

It would be of practical value to know (1) whether any of your correspondents have made a practice of having the injection site massaged gently for half an hour or so after administration with a hot (or very warm) water bottle; (2) how many of your correspondents utilize the quadratus femoris muscle for any intramuscular injections (soreness in the thigh does not as a rule impede sitting or writing); (3) whether therapists in this and other medical fields have found it possible to obtain a wide canvass of the views of colleagues who have both suffered an attack of the condition and also treated it in patients.

—I am, etc.,

Jamaica.

K. C. ROYES.

SIR,—I have been very much interested by the correspondence on the subject of quinine injections, as, in the course of the past three years in a highly malarious district, I have had a fairly large experience of their use and abuse.

My own initial reaction on arriving in this area to the practice of giving quinine by injection intramuscularly was wholeheartedly to condemn it, as our out-patient department was very seldom without a case which had developed an abscess as a result of an injection given by outside practitioners. I may say that, having probably handled several thousand cases as out-patients who have had quinine injections intragluteally, I have never seen a case of tetanus which could be attributed to the injection.

I would agree with Dr. Harrison (December 8, 1951, p. 1403) when he attributes the efficacy of the injection method

to the slow absorption from the injection site. Quinine is still our main method of attack against malaria, and I have been very disappointed with proguanil in attacks of malignant tertian malaria. The nausea and vomiting so often associated with severe attacks make oral administration very uncertain. The ability to create a reservoir of quinine by daily injection given about an hour before sporulation is the surest method I have found of checking a severe attack and of giving a low relapse rate.

The three important factors I have found which prevent any severe local or general effects from an intragluteal injection are the type of quinine salt (we always use the dihydrochloride as being the least toxic locally), the sterility of syringe, needle, and skin, and the site of injection. This last is very important, as many injections which have gone wrong in this hospital have been traceable to the habit of giving them too high in the buttock, into subcutaneous fat. Quinine must be injected deeply intramuscularly.

Over the past three months, when about 200 were given here, there has been no case of gluteal abscess, as these three factors have been carefully observed. Previous mishaps were due mainly to lack of care in the last.

I would personally attest to the value of intragluteal quinine injections, as I had a course of daily injections during a severe attack of malignant tertian which occurred despite prophylactic proguanil. A small, sterile necrotic area appears to be formed, from which absorption occurs, probably over about eight weeks.

I would like to emphasize that so long as the injections are given in a careful manner, realizing the inherent dangers, quinine dihydrochloride by intragluteal injection has a very definite place in malarial therapy, especially in M.T. infections.—I am, etc.,

Rajshahi, East Pakistan.

IAN T. PATRICK.

SIR,—In his letter in your issue (January 26, p. 220) Colonel Harrison, I think, misses the main point which I endeavoured to make in mine in that of January 12 (p. 104). This was that the injection of quinine is a valuable life-saving measure in an emergency, but should, in my opinion, be reserved for such occasions, and that the intravenous route should be employed if an accessible vein can be found, and the intramuscular method used only when this is not so.

In cerebral malaria, where rapidity of action is vital, it is generally agreed that the intravenous route is the only useful one, and in such cases a vein must, if necessary, be exposed. But cerebral malaria, though the chief, is not the only, indication for injection therapy: the algid and haemorrhagic types of subtertian malaria among others can produce grave emergency, uncontrollable per os and fully justifying injection. My thesis is that in these cases also the intravenous route is that indicated, though I would not claim that the indication is so absolute as to call for the exposure of a vein if none can otherwise be found. But I cannot agree that a procedure which demonstrably causes necrosis of tissue is called for in the ordinary uncomplicated case of acute malaria. Still less, *pace* Colonel Harrison, is it indicated in chronic cases.

Fortunately the point is nowadays almost academic, for the synthetic antimalarials, now in general use, are extremely efficacious in these cases. There are injectable preparations, on the market which can safely be given intramuscularly, and the blood levels, I am informed, can relatively easily be determined.

I agree entirely with Colonel Harrison on the need for training medical subordinates in good intramuscular technique generally, but would point out that this is more easily secured in military units with their greater centralization than in civil districts with their scattered dispensaries and more exiguous staff.—I am, etc.,

London, S.W.1.

J. B. HANCE.

Carcinoma of the Stomach

SIR,—Drs. B. F. Swynnerton and S. C. Truelove, in their interesting survey of carcinoma of the stomach (February 9, p. 287), tell us that a barium meal is the most accurate single diagnostic procedure. Unless I have misread them, their follow-up was of positive findings, and they have no means of being sure how many cases with negative radiology died elsewhere of gastric neoplasms. One finds doctors

naturally reluctant to make such a diagnosis after a normal skiagram, so that these cases tend to escape notice, but they are not rare and should be taken into account. During the past four years I have seen seven patients dying of gastric cancer, in each of whom a barium meal at the onset of symptoms was reported as normal by a competent radiologist, and this is a much larger fraction of my experience of the disease than the 10% of radiological failures recorded by your correspondents. Final diagnosis rested on laparotomy or necropsy. No blame attaches to the various radiologists, who in some types of growth are set an impossible task, but before we can improve the results of treatment of this condition we must have a more reliable means of confirming our clinical suspicions.—I am, etc.,

London, W.1.

C. P. PETCH.

SIR,—The paper by Drs. B. F. Swynnerton and S. C. Truelove (February 9, p. 287) on carcinoma of the stomach contains much interesting information but one notable fallacy. It compares survival rates in two groups of patients which are, as the authors themselves admit, not comparable. The groups contain, respectively, the growths which were advanced and those which were still (irrespective of the length of history) in an early stage: or, in brief, the hopeless and the hopeful. It is not the fact that a growth was resected but that it was resectable that, as their work shows, influences the period of survival.—I am, etc.,

Hove.

CONSTANCE M. OTTLEY.

Methonium Compounds and Muscle Relaxants

SIR,—Drs. F. C. MacIntosh and W. D. M. Paton (*J. Physiol. Lond.*, 1949, 109, 190) have reported that, in the cat with autonomic ganglia blocked chemically by nicotine tartrate or tetraethylammonium iodide, the intravenous injection of D-tubocurarine or dimethyltubocurarine causes a fall in blood pressure due to histamine release.

The methonium compounds, which act by blocking the autonomic ganglia, are now being used in anaesthesia to produce controlled hypotension. It would be interesting and also important to know if anyone has observed a further fall in blood pressure or prolonged hypotension occurring, following the injection of muscle relaxant, in patients on whom the above technique has been used.—I am, etc.,

Glasgow.

W. SNIPER.

Nomenclature of Diseases and Operations

SIR,—I read with much interest the letter of Dr. W. A. Bourne (February 9, p. 330). I agree with Dr. Bourne that the American *Standard Nomenclature* is superior for clinical purposes to the *International Classification*. Although I can only speak with any authority on my own subject of ophthalmology, I have used the *Standard Nomenclature of Diseases and Operations* for the last few years to classify general extracts from the literature and have found it most helpful. It follows a logical system in which diseases are considered, first by their anatomical location; and secondly by presumed aetiology; three numerals are allotted to the first group and three numerals to the second, with extension of this where greater detail is necessary.

The new (4th) edition which I received recently is an advance on previous ones, particularly in relation to toxic conditions, and usefully gives the *International Classification* in an appendix, so that the two may be compared. It is at once obvious how meagre the *International Classification* is for clinical purposes, some hundred different eye conditions being included under the joint heading of "other diseases of eye." I can see little reason why the *Standard Classification* could not be used for broad statistical analysis in addition to its use for more detailed clinical analysis, if classes can be grouped—say, by the first two digits anatomically and aetiologicaly. Possibly it is not immediately adaptable in its present state. For example, I noted that there is no inclusive heading for "All causes of pulmonary oedema," "All causes of cirrhosis," "All causes of eosinophilia," or

"All causes of jaundice." I realize, of course, that these are purely symptomatic diagnoses and include many very varying diseases. The American system, with its insistence on an attempt at exact aetiology, possibly precludes a classification on a symptomatic basis. Is this the kind of grouping that administrators need, or is an aetiological one not as good or better?—I am, etc.,

AGT.

W. O. G. TAYLOR.

SIR,—Dr. W. A. Bourne (February 9, p. 330) has found the *International Statistical Classification of Diseases, Injuries, and Causes of Death* unsuitable for the clinical purposes in which he is interested, and has suggested that the World Medical Association might appropriately consider a combined clinical and statistical system. The international statistical classification, like the obsolete *Provisional Morbidity Classification* of the Medical Research Council (1944), was not primarily designed either as a nomenclature of diseases or as a diagnostic index for clinical recording and research. For purposes of nomenclature there is already in this country the admirable *Nomenclature of Disease* of the Royal College of Physicians (7th ed., 1948).

The need for a diagnostic index for clinical purposes, particularly in respect of hospital records, has been recognized by the Registrar-General's advisory committee on medical nomenclature and statistics. The committee considered that the international classification might well form the basis of such a diagnostic index. Accordingly a subcommittee has recently been appointed to examine the possibility of adapting the international classification for this purpose. Already the subcommittee has inquired from a number of hospitals known to be using it how far it has been found suitable as the basis for a diagnostic index, and what adaptations have been found necessary to meet the needs of particular specialties.

It would be of considerable help to the subcommittee if clinicians would bring to my attention any shortcomings of the international classification for the clinical purposes in which they are interested, together with their suggestions for its expansion or modification.—I am, etc.,

General Register Officer,

Chief Medical Statistician.

POINTS FROM LETTERS

Treatment of Tropical Ulcers

Dr. T. C. HALLINAN (Jamaica, B.W.I.) writes: I was very interested in the article by Dr. H. D. O'Brien (December 29, 1951, p. 1544). I was quoted as having treated 15 cases of small tropical ulcers, and an indefinite number of large ones. In fact, in my original article the only figure I mentioned was a total of 188 cases. In actual fact 87 of these were small ulcers and the remaining 101 were medium (2 to 3 in. (5 to 7.5 cm.) diameter) or large (4 in. (10 cm.) or larger). I now have a total of 1,023 cases treated, and my results remain the same, in time of healing, as mentioned in my original article. One thing, however, I did not mention in the article is that almost all of my cases receive ambulant treatment and go about their normal work during the period of treatment, and even my worst cases could resume work within two weeks or less of commencing treatment, with only two exceptions, in whom ulcers involved a large part of the heel and sole of the foot, baring both bone and tendon. These took six weeks before resuming work. The dressings were applied only once a week, preferably one in two weeks, and are very simple in application, not needing a skilled dresser. Thus the loss of man-power and earning capacity on the part of the workers is almost negligible, and there is also great economy in dressings and doctors' time. One other fact has been observed recently—that if no yeast or other form of vitamin-B complex is taken the ulcers take at least half as long again to heal. This supports the theory that these ulcers are basically a nutritional deficiency disease.

Correction

Owing to a printer's error the word "arthritis" was substituted for "arteritis" in the penultimate line of the letter on diabetic gangrene from W.A.E. and E. V. Shute in our issue of February 2 (p. 276).

Obituary

Sir RICHARD LUCE, K.C.M.G., C.B., F.R.C.S.

We record with regret the death, which took place on February 22, of Major-General Sir Richard Luce, for many years senior surgeon, and later consulting surgeon, to the Derbyshire Royal Infirmary.

Richard Harman Luce was born in 1867 at Malmesbury, Wiltshire, the son of an Army colonel. He went to school at Clifton College, and from there went on to Christ's College, Cambridge, taking the B.A. with first-class honours in the Natural Sciences Tripos of 1889. In that year he entered as a student at Guy's Hospital, and qualified in 1893. He proceeded to the degrees of M.A., M.B., B.Ch. in the same year. After a period as house-surgeon and obstetric registrar at Guy's and another house-surgeoncy at York County Hospital, he began surgical practice in the North Midlands, making his home at Derby. He took the F.R.C.S. in 1894.

[Press Portrait Bureau]

From 1909 to 1913 he was A.D.M.S., North Midland Division, Territorial Force, and in the war which began in 1914 he served in Palestine, Gallipoli, and Egypt, becoming, in 1918–19, Director of Medical Services, Egyptian Expeditionary Force, with the rank of major-general. He rendered conspicuous service in the war, was mentioned in dispatches, and was invested with the C.B. (military) in 1916, the C.M.G. in 1918, and the K.C.M.G. in 1919.

In 1924 Sir Richard Luce entered Parliament as Conservative Member for his adopted city of Derby. His election for such a constituency, the stronghold of one of the then leaders of the Labour party, must be ascribed to his personal popularity, for the other Conservative candidate who ran with him for the two-member seat was some thousands below him at the poll. He did quiet but good work in the House of Commons, and was a useful accession to the Parliamentary Medical Committee, but he failed to retain his seat at the next general election in 1929.

In Derby he built up a sound reputation as an operating surgeon, and in addition to his work at the Royal Infirmary, where he was energetic in promoting plans for new buildings, he was surgeon to the Derbyshire Hospital for Sick Children and consulting surgeon to the Ripley and Wirksworth cottage hospitals. He served as medical referee under the Workmen's Compensation Act in the Derby county court circuit.

For some years Sir Richard Luce had a seat on the Council of the B.M.A., and he gave long and patient service to its Hospitals Committee, of which he was chairman. It fell to his lot to pilot some large revisions of hospital policy through the meetings of the Representative Body in the early nineteen-thirties, and, although he was not a man who cultivated the platform, he showed quite extraordinary skill, foresight, adaptability, and openness of mind in dealing with a most intricate

and often tiresome subject. In addition to this work he also served for a term as president of the Midland Branch and chairman of the Derby Division of the B.M.A.

After his retirement from hospital and consulting practice in Derby, Sir Richard Luce went to live in Hampshire, the native county of his wife, who was the daughter of Sir John Scott, of Bournemouth. They had five children—three daughters and two sons, the younger of whom died in India. One of Luce's first activities in retirement was to write a history of the old Benedictine monastery in his native town of Malmesbury. Archaeology shared with music his recreational interest, and he was president of the Hampshire Field Club and Archaeological Society. In later years he became an authority on the history of Romsey Abbey, and published a book on the subject in 1948. He himself helped in the work of making tapestries needed for the restoration of some of the Abbey's furniture. It was inevitable that his fellow citizens in Romsey would elect him to the borough council, and he was mayor of the town from 1935 to 1937. In addition he was a co-opted member of the health committee of the Hampshire County Council. He was chairman of the Hampshire County Medical Advisory Committee and county controller of the V.A.D.s. Few men can have had a more active "retirement."

Always modest and kindly in demeanour, and sparing himself no pains to be of service to his colleagues and his patients, he was most popular among them, and although he went into politics it is to be doubted whether he ever had a single enemy. Some will remember, years after his retirement from active participation in Association affairs, the great welcome he received from his old colleagues when he appeared at the Annual Meeting of the Association at Plymouth in 1938.

Dr. Hugh Barber writes: When I first knew Richard Luce, in 1906, he had been established in Derby for 11 years. Holding the post of honorary surgeon to the Derbyshire Royal Infirmary, he was accepted by the medical profession as the leading consulting surgeon in the district. At the same time he was engaged, single-handed, in a busy general practice. He would be driven round in his dog-cart in the morning until towards lunch-time, when he would visit the hospital. For his out-patient session once a week, which began at noon, he was always punctual, as also for his operating sessions, which would be in the afternoon. During his emergency week he would cycle to hospital to operate in the evening or at night. Although, like the majority of the profession, he changed from horse transport to a motor-car in 1906, he still used a bicycle for emergencies, because cars had not the conveniences or reliability which we know to-day.

It is true to say that he succeeded in both general practice and consulting work. He was quick by temperament, making up his mind to the correct decision without delay. His patients knew that they could not detain him unnecessarily, but that nothing essential for their care or comfort would be neglected. In hospital he gained the respect and affection of colleagues, residents, nursing, and administrative staff. Although an influential member of the hospital board, he had little time for committee work, but gave his advice freely behind the scenes. Understanding the anxieties of a general practitioner, he was a delightful colleague to call in for a difficult problem. In taking a history he would go straight to the root of the matter and keep others to the point. On one occasion, when questioning a man about a pain not very well defined, he was interrupted by a wife prepared to describe her husband's symptoms. His immediate response—"You cannot tell me if he can't"—was accepted as a reasonable correction by a woman who could realize that the case was in good hands.

After his distinguished war service from 1914 to 1918—which was the outcome of his former work as a Territorial—he returned with well-deserved honours and confined himself to consulting surgery. Two years before reaching the age when his retirement from hospital work was due he was invited to stand for Parliament as Conservative candidate, and his election in 1924 was a tribute to his high reputation in the town rather than to fixed political principles. He was a man of exceptional energy and enthusiasm, but always courteous. He earned the gratitude of many patients, a large number of whom were doctors or their relatives. Outside his professional work he was gifted in music and art. His success as an Army administrator was only to be expected.

Sir FRANK GUNESSEKERA, C.B.E., M.R.C.S.

The sudden death of Sir Frank Gunesequera while attending a reception at the Governor-General's residence in Colombo on January 23 came as a shock to his family and to his numerous friends and patients throughout the length and breadth of Ceylon.

Frank Arnold Gunesequera was born on November 14, 1887, the son of the late Mr. Francis Gunesequera, J.P., and was educated at the Royal College, Colombo, and at the Ceylon Medical College, from which he qualified in 1910. He held the post of house officer at the General Hospital, Colombo, for one year, and then proceeded to England for further medical studies at the London Hospital Medical School, taking the M.R.C.S., L.R.C.P. in 1913. Returning home immediately, he was in private practice in Colombo, and for very many years until his death had one of the busiest practices in Ceylon. In 1914 he was commissioned in the Ceylon Medical Corps and was medical officer in charge of the combined hospital for British, Australian, and Sinhalese Servicemen

during the 1914-18 war. He was appointed O.B.E. (Military Division) in 1935, was awarded the Efficiency Decoration in 1936, and was Commanding Officer of the Ceylon Medical Corps from 1935 to 1939. In 1937 he represented the Ceylon Defence Force at the Coronation of the late King George VI, and in 1938 was appointed Honorary Surgeon to the Governor of Ceylon, being the first medical man in Ceylon to receive the honour.

With the creation of an Upper House in the new Dominion of Ceylon, established in 1947, Sir Frank Gunesequera was nominated by the Governor-General, on the recommendation of the Ceylon Branch of the British Medical Association, to represent the professions in the Senate—a fitting tribute to a highly respected member of the medical profession. His services to the State were soon recognized and he was appointed C.B.E. (Civil Division) in 1948. Thus he became the recipient of an appointment in both the Military and Civil Divisions of the Order of the British Empire, receiving special permission to wear both insignia. In 1950 he was created a knight, an honour he regarded as a tribute to the profession of his country. Shortly before his death the Upper House elected him Deputy President of the Senate.

for instant hot water

Hot water for washing — hands, instruments, utensils — in surgery, ward and hostel — the need is constant. Ascot gas water heaters meet that need — cheaply. They are fully automatic, they give hot water instantly and in endless quantity, and they use gas only while hot water is running.

The RS 52/1 is of particular value.

It provides water controlled by a knob at warm, hot or *boiling*; certified by public analyst to be fit for human consumption.

See the full range of Ascot heaters at any gas showrooms or write for illustrated leaflets to

Sir Frank Gunsekera took a leading part in the medical affairs of Ceylon, and was particularly interested in maintaining a high standard of professional ethics. An enthusiastic member of the Ceylon Branch of the British Medical Association, he was its president in 1931-2. He was also a member of the Ceylon Medical Council since its inception in 1925, and had been its vice-president since 1933. He served on numerous committees. As a member of the Ceylon University Court, University Council, and the Faculty of Medicine, he expressed his views forcibly and frankly. In addition, he will be remembered always as an ideal practitioner and as a lovable and upright man. With his personality and charm, Sir Frank Gunsekera had thousands of patients, both rich and poor, who came to him from all parts of Ceylon for advice and treatment, and who left him carrying with them an everlasting affection and regard. An engraved card found in his notebook after death bore testimony to his ideals. On it were the words: "The glory of life is to love, not to be loved. To give, not to get. To serve, not to be served. To be a strong hand in the dark to another in the time of need. To be a cup of strength to any soul in a crisis of weakness. This is to know the glory of life." The funeral of one of the most beloved physicians of Ceylon took place on January 24 at the General Cemetery, Colombo, in the presence of a large gathering of mourners.

Sir Frank Gunsekera leaves a widow, four sons, two of whom are members of the medical profession, and two daughters. We offer our deepest sympathy to them.—O. E. R. A.

W. J. ELFORD, Ph.D., F.R.S.

By the death of Dr. William Joseph Elford on February 14 at the early age of 52, medical science lost one of the pioneers in virus research.

Born in 1900, Elford spent his early life and school-days in Malmesbury in Wiltshire. He gained a scholarship to Bristol University, where he graduated B.Sc. in 1923. His research career began under Professor J. W. McBain, F.R.S., during tenure of a Colston research fellowship. In 1925, after he had proceeded to the degree of Ph.D., he joined the scientific staff of the National Institute for Medical Research at Hampstead as a physical chemist to be mainly concerned with problems in virus research. This appointment was soon to bear fruit. Elford developed in the mysteries of virus diseases an absorbing interest which he was never to lose.

Very little was known at this time about the filter-passing viruses, until Elford developed a method for measuring their size. This he achieved by filtering the virus through an accurately calibrated series of collodion membranes of graded pore size. His "gradocol" membranes became widely known and used in virus laboratories. Subsequent development of the electron microscope has provided confirmation by direct measurement of the accuracy of his method. During the war he applied his knowledge of physical chemistry to the study of air disinfection and the production of aerosols. Later he renewed his early interest in bacteriophage, and began to investigate the interaction of penicillin and bacteriophage upon staphylococci. In 1949 Elford published his remarkable electron micrographs of the recently isolated strains of influenza virus adsorbed upon the laked chicken red cell. These photographs showed the presence of new "long forms" of the virus and were of extreme interest.

His election in 1950 to the Fellowship of the Royal Society was richly deserved and undoubtedly gave him great pleasure. It is a tribute to his inventive genius that his two major contributions to science—the gradocol membrane and new electron microscopical method for virus research—have been key techniques which open up relatively easy access to much vital new knowledge.

To his colleagues William Elford presented a quiet and retiring personality, while his closer collaborators found he possessed scientific enthusiasm and a capacity for painstaking critical investigation second to none. A kinder or more pleasant teacher would be hard to find. The generous and helpful attitude he showed to his numerous scientific visitors was in part responsible for the large number of callers he received; with all his friends and co-workers he maintained a very extensive correspondence. The output of work published on his own or in collaboration with others was very considerable, and behind it lay a vast amount of information and experience gained in nearly thirty years of research. He applied the most exacting standards to his work before publishing any results, and this fact was reflected in his scientific reputation, which was of the highest order. On entering his laboratory one was always impressed by its extreme tidiness, however busy the day or complex the experiment; though in many respects a necessity, this tidiness was no mean achievement in research embracing physical, chemical, and microbiological studies of infectious and frequently virulent material. Elford was a master in all these fields. Although he had received no biological training, it came as a surprise to many of his co-workers to learn that he did not possess a medical degree; however, he was always content to leave animal experimentation to his medically qualified colleagues.

In recreation Dr. Elford was as active as in his work. Keenly interested in all branches of sport, he was an excellent cricketer and tennis player. He played a prominent part in the origination and organization of the Institute's athletic association. When a breakdown in health had put an end to his active participation in games he still continued to be a frequent visitor to Lord's, Wimbledon, and Twickenham. His early death will be keenly felt by his friends throughout the world: but Elford would surely have preferred a sudden end to a long separation by illness from his work, for this was his life.—J. E. H.

Dr. F. H. ROBBINS died very suddenly, of coronary occlusion, at his home in London on December 25, 1951, after having appeared to be in vigorous good health. Frank Hubert Robbins was born in 1887, the son of a distinguished dental surgeon. He was educated at St. Paul's School, Pembroke College, Cambridge, and St. Bartholomew's Hospital. His quiet, earnest manner as a student earned him the nickname of "Razzle." He graduated B.A., with first-class honours in the natural sciences tripos, in 1909, and qualified M.R.C.S., L.R.C.P. in 1912. The next two years were spent in house appointments at St. Bartholomew's Hospital. In the war of 1914-18 he joined the 85 Field Ambulance, R.A.M.C., T.A., and served in France, Salonika, and Gallipoli, and was awarded the Military Cross. (At his funeral his coffin was covered with the Union Jack that had flown wherever his ambulance was stationed.) On demobilization he studied further and obtained the F.R.C.S.Ed. in 1920 and the B.M., B.Chir. in 1923. He first practised at Leatherhead in Surrey, but very soon took over the late Dr. O. C. Shaw's practice in Golders Green,

where he remained until his death. His appointments included those of surgeon to the Post Office, Treasury medical officer, chairman of a National Service medical board, and medical officer to the Hendon District Hospital. He was chairman of the Hendon Division of the British Medical Association in 1934-5, and he often represented the Division on the Metropolitan Counties Branch council. It was in committee that his sane advice was most appreciated. To his colleagues, who were deeply shocked by his death, he was looked upon as the ideal general practitioner and a most strict observer of medical etiquette in the best sense. He was a devout Christian, a good Freemason, and was a Past Master of the Rahere Lodge. The latter part of his life was marred by the death of his son Anthony, a promising medical student, who died of infantile paralysis in Snowdonia while out with the Cambridge Climbing Club. He was further distressed when his other son was affected by the same disease, but happily only mildly. Because of his sufferings he was able to give wise and sympathetic help to all those who sought his advice. He will be greatly missed and long remembered by his patients, his colleagues, and by those who loved him.—C. B. W.

Dr. SAMUEL STUART BROWN, who died suddenly on January 15, was educated at Ravenscroft School and at the Royal Belfast Academical Institution and Queen's University, Belfast, where he graduated M.B., B.Ch. (with honours) in 1923. Soon afterwards he took over a large general practice at Fulham, in London, where he held appointments as police surgeon, medical adviser to the Chelsea Football Club, and physician to an L.C.C. orphanage. In 1936 he returned to Belfast and rapidly built up a large practice, work in which was interrupted by the war years, when he served for a long period overseas, including Burma, with the Royal Air Force, retiring with the rank of squadron leader. On returning, his practice became larger than ever, and since the inception of the National Health Service he had been overworked. He retained his interest in children by becoming honorary physician to one of Dr. Barnardo's homes. Added to his other work, he threw himself wholeheartedly into the affairs of the British Medical Association, and, as honorary secretary of the Northern Ireland Branch since 1949, he had carried a great portion of the responsibility for Ulster. For the last three years he had represented his constituency at the Annual Representative Meeting. In his younger days Dr. Brown was a keen athlete and a fine rugby player. He represented his province in the schools' interprovincial games, and later was one of the best forwards playing in senior rugby. He carried his enthusiasm to London, and his advice was early sought by the local club. Latterly golf had been his game, and, although very busy in his practice, he usually found some time for it. He not only enjoyed the game itself but was very popular on the social side, for with his fine, commanding appearance and his attractive manner he made friends wherever he went. His funeral, one of the largest seen for a long time, was a testimony to the love in which he was held in the east end of Belfast. Dr. Brown is survived by his wife, a daughter, and a son, now a second-year medical student, and to them we offer our deepest sympathy.—I. F.

We announce with regret the death on January 28 of Dr. ROBERT MOORE FRASER at his home in Knock, Belfast. Dr. Fraser was born in 1865, and was educated at the Royal Belfast Academical Institution and at Queen's College, Belfast. He graduated B.A. at the old Royal University of Ireland in 1885, and took the M.B., B.Ch. degrees five years later, proceeding M.D. in 1920. Dr. Fraser, who had lived in retirement for some time, had carried on an extensive practice in Knock and district for nearly 50 years. A man of many interests, he was the Ulster representative on the committee of the *Scottish National Dictionary*, and retained to the end his love of the classics. He was keenly interested in world affairs, especially European politics, and took a

leading part in the historical section of the Presbyterian Church. In his own church at Knock he was the senior elder. He was a staunch Unionist, and in the 1914-18 war took an active part in the work of the Ulster Volunteer Force Hospital. Of a quiet, reserved nature, he was a staunch friend and a delightful companion. He was twice married, first to Miss Margaret Ferguson, of Muckamore, and secondly to Miss Alice Cuthbert. He is survived by his wife; one son, Ian Fraser, the Belfast surgeon; and his daughter, Margaret.

Medico-Legal

NO VACANT BEDS

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

How far the hospital service falls short of requirements was shown vividly by a recent inquest at Leeds. An elderly retired labourer complained for many months of steadily increasing pain, sometimes round the heart, sometimes in his trunk and legs. At length he became bedridden and sleepless. He was a widower, and so his care fell heavily upon his three sons and the young daughter of one of them. His family doctor, who saw him for his pains in the middle of January, thought he should see a specialist, and gave him an appointment card for the orthopaedic department of the Leeds General Infirmary. The department replied that an appointment with a specialist could not be arranged for about eight weeks. The doctor then gave the sons a note to St. James's Hospital for the patient's admission, and he was put on its "priority list." Next week, as the hospital would give no definite promise of admission, the doctor had him seen by a specialist, who said he would take the patient into hospital as soon as a bed was available. More weeks went by and the patient still could not enter hospital. The doctor saw him weekly, pressed the specialist's secretary to hasten admission, and gave him a note for the hospital almoner. On March 17 the patient, trying to turn himself over in bed, fractured his left femur. For this acute condition the doctor's assistant was able to send him at once to the infirmary, but he died soon after arrival.

The necropsy showed that the cause of death was a carcinoma of the lower lobe of the left lung, with metastases scattered throughout the liver, spleen, and mesentery. The fracture had been due to a deposit just below the lesser trochanter.

At the inquest the sons were resentful of what they called the neglect of their father, and blamed the doctor; but he was able to show that he had paid 11 consecutive weekly visits before the end, had prescribed palliatives, and had done his best to secure proper attention for the patient. He pointed out that at times he had had 20 patients on priority awaiting their turn, some in at least as serious a condition as the deceased. The medical superintendent at St. James's Hospital said that the male waiting-list at the date of the inquest was about 150 and the priority list 42. The patient had been placed on the priority list in 50th place as soon as his request for admission had been received, and at his death he had been eighth. The female waiting-list was 200. The only remedy was more beds and more nurses, which meant more buildings. There was no waiting-list before the war. He suggested that more women were working now and that they were no longer able to look after their own ailing relatives; the population's longer life meant more elderly patients, and perhaps doctors were sending more patients to hospital under the Health Service. Dealing with the waiting-list, he remarked, was his "worst job." The deputy house governor at the infirmary testified that male patients had been waiting on its priority list for two or three months and female for five to six months. The verdict was death from natural causes.

Medical Notes in Parliament

Abolition of Identity Cards

In answer to a question in the House of Commons on February 21 the MINISTER OF HEALTH announced that it was no longer necessary for the public to possess and produce an identity card or to notify change of address for National Registration purposes, although the numbers would continue to be used in the National Health Service. Numbering was necessary in the National Health Service in order to identify patients and to avoid inflation of doctors' lists of patients. To save the labour and expense of allotting new numbers the old National Registration numbers would be retained for this purpose. Anyone using the Service would be asked, as now, for his number when applying to go on a doctor's list or for dental or ophthalmic treatment.

Connaught Military Hospital

Mr. F. F. A. BURDEN on February 21 drew attention to the conditions at the Connaught Military Hospital for tuberculous patients at Hindhead, Surrey. Mr. A. HEAD said the accommodation at this hospital was not all that he would wish. If, however, it were not used, tuberculous patients would have to wait for a bed in the limited general hospital accommodation elsewhere and would not have the advantage of early specialist treatment. Further improvements in the structure and amenities were in hand. Recent allegations about the conditions were much exaggerated.

Cost of Patients' Food

Mr. N. N. DODDS on February 21 spoke of the concern caused by the decision of the South-west Metropolitan Regional Board controlling over 300 hospitals to spend no more than 21s. a week on feeding each patient. Mr. H. F. C. CROOKSHANK replied that the board asked management committees, in preparing their estimates for the next financial year, to regard as maxima for their groups certain figures of expenditure on provisions based on averages in the region. In addition it warned committees to take account of possible price rises in framing their estimates. This was an interim measure pending a further detailed investigation into the costs of provisions. On the information at present available he saw no reason to intervene.

Sanatoria Waiting-lists.—Provisional figures show that the number of persons waiting to enter tuberculosis sanatoria in England and Wales at December 31, 1951, was about 8,200.

Surgical Boots.—It is proposed to make a fixed charge of £3 a pair for surgical boots and shoes.

Estimates.—Mr. Crookshank states that it seems probable that in 1951-2 expenditure on the general dental services as a whole will be about equal to the estimate, while that on the supplementary ophthalmic services will be about £5m. below. In Scotland expenditure on the latter is expected to be about £50,000 below the estimate.

Universities and Colleges

UNIVERSITY OF OXFORD

Charles Joseph Singer, D.M., D.Litt., F.R.C.P., Professor Emeritus of History of Medicine in the University of London, has been elected to an Honorary Fellowship of Magdalen College, Oxford.

UNIVERSITY OF CAMBRIDGE

The Copeman Medal for medical research of Corpus Christi College has been awarded to Dr. John Chaplin Sloper.

The following medical degrees were conferred in Congregation on February 8:

M.D.—A. A. Miles, J. Lister, H. T. H. Wilson, J. R. Robinson. M.B., B.Chir.—*D. B. Murray, *N. R. Lewis, *E. M. Spröston.

Professor B. H. C. Matthews, F.R.S., Professor of Physiology in the University, has been elected to a Professorial Fellowship of King's College.

Dr. T. S. Hele, formerly Master of Emmanuel College, has been elected into a Life Fellowship of the College.

*By proxy.

UNIVERSITY OF ST. ANDREWS

The honorary degree of LL.D. will be conferred on Emeritus Professor R. C. Alexander, formerly Professor of Surgery, and on Emeritus Professor Adam Patrick, formerly Professor of Medicine, in the University at a graduation ceremony on July 4.

UNIVERSITY OF LEEDS

At a meeting on February 20 the Council of the University recorded its deep regret at the death of His Majesty King George VI, the Visitor to the University, and the Pro-Chancellor read the letter and resolution of the Senate and the Council which had been forwarded to Her Majesty the Queen by the Chancellor.

The following appointments were announced: I. M. P. Dawson, M.B., B.Chir., M.R.C.P., as Lecturer in Pathology, and C. O. Carter, B.M., B.Ch., M.R.C.P., as part-time Medical Geneticist. Professor R. D. Passey, Head of the Department of Experimental Pathology and Cancer Research in the University, has received the following letter from the trustees of the Anna Fuller Fund of New Haven, Connecticut, U.S.A.:

"The trustees of the Anna Fuller Fund, at their meeting on February 8, 1952, on their own motion, voted a gift in the amount of one hundred pounds to the University of Leeds, in memory of King George VI. The trustees specifically provided that this gift needs no acknowledgment or special accounting, but may simply be used, in whole or in part, at any time or from time to time, for any purpose having to do with cancer research in your complete and unfettered discretion."

It is proposed to devote the money towards the cost of the electron microscope recently installed in the department.

The Services

Surgeon-Commanders A. F. M. Barron and D. J. N. McNab, R.N.V.R., Surgeon Commander C. A. Pittar, R.N.Z.N.V.R., and Surgeon Lieutenant-Commanders O. J. Vaughan-Jackson, F. G. Ward, and T. B. Snell, R.N.V.R., have been awarded the Royal Naval Volunteer Reserve Decoration.

Brigadier G. E. MacAlevey, C.B.E., D.S.O., M.C., late R.A.M.C., has been appointed a Deputy Director of Medical Services of the Army and has been granted the temporary rank of Major-General.

Lieutenant-Colonel (Temporary Colonel) Sir Arthur Porritt, K.C.M.G., C.B.E., R.A.M.C., T.A., has been appointed Honorary Colonel of a T.A. unit in succession to Colonel Lord Webb-Johnson, K.C.V.O., C.B.E., D.S.O., T.D., R.A.M.C., whose tenure has expired.

A Supplement to the *London Gazette* has announced the following awards:

First, Second, and Third Clasps to the Territorial Efficiency Decoration.—Major (Honorary Colonel) T. A. A. Hunter, R.A.M.C.

First and Second Clasps to the Territorial Efficiency Decoration.—Major (Honorary Lieutenant-Colonel) J. R. Wright, T.D., and Major A. D. Briscoe, T.D. (now Supplementary Reserve), R.A.M.C.

Territorial Efficiency Decoration and First Clasp.—Majors P. T. Cooper, J. C. Fletcher, J. B. Mackay, M.B.E., and C. S. Nicol, R.A.M.C.

Territorial Efficiency Decoration.—Major (Honorary Lieutenant-Colonel) A. G. Hammond and Honorary Major D. S. Macpherson, retired, R.A.M.C.

The President of the U.S.A. has conferred the Silver Star Medal upon Major D. H. R. Montgomery, M.C., R.A.M.C., and the Bronze Star Medal upon Lieutenant-Colonel A. MacLennan, O.B.E., R.A.M.C., in recognition of gallant and distinguished services during the operations by the United Nations in Korea.

The Prince Regent of Belgium has conferred the following decorations in recognition of distinguished services in the cause of the Allies during the 1939-45 war:

Commander of the Order of Leopold II.—Brigadier (Honorary) R. R. G. Atkins, O.B.E., M.C., late R.A.M.C.

Officer of the Order of Leopold.—Lieutenant-Colonel J. Smith, O.B.E., T.D., R.A.M.C.

Croix Militaire 1st Class.—Lieutenant-Colonel J. V. Bradley, T.D., and Major J. K. Willson-Pepper, R.A.M.C.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending February 9 (No. 6) and corresponding week 1951.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available. The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

CASES in Countries and London	1952					1951

* Measles not notifiable in Scotland, whence returns are approximate.

† Includes primary and influenza pneumonia.

§ Includes puerperal pyrexia.

Vital Statistics**Smallpox in Lancashire**

Up to and including February 22 a total of 40 confirmed cases of variola minor have been reported from Rochdale (38 cases) and the adjoining town of Milnrow (2 cases). Of these 40 patients, 23 developed their disease in February; in 17 patients the illness was diagnosed retrospectively. All medical officers of health have been warned of the presence of this disease in south-east Lancashire by the Chief Medical Officer, Ministry of Health.

Infectious Diseases

Infectious diseases increased in incidence in England and Wales during the week ending February 9. The largest rises in the number of notifications were measles 1,039, dysentery 102, acute pneumonia 100, scarlet fever 96, and whooping-cough 34.

The increase in the incidence of measles was mainly contributed by the northern section of the country; the largest rises were Lancashire 286, Warwickshire 129, Durham 106, and Yorkshire East Riding 101. A small rise in the number of notifications of scarlet fever was recorded in every region of the country, but no large local fluctuations occurred. The only large variations in the trends of whooping-cough were an increase of 84 in Yorkshire West Riding and 65 in Staffordshire. The number of notifications of diphtheria was 10 more than in the preceding week; these cases were scattered throughout the country. The largest returns of diphtheria during the week reviewed were Warwickshire, Birmingham C.B. 6, Lancashire, Darwen M.B. 5, and Liverpool C.B. 3.

The number of notifications of acute poliomyelitis was 6 fewer for paralytic and 2 fewer for non-paralytic cases than in the preceding week. The largest return was 4 in Yorkshire West Riding. No multiple cases were recorded in administrative areas.

The notifications of dysentery were the largest for 33 weeks. A further 83 cases were notified from the outbreak in Norwich C.B. The other large centres of infection during the week were London 82 (Wandsworth 23, Hackney 12, Islington 12); Lancashire 71 (Oldham C.B. 19); Yorkshire West Riding 63 (Leeds C.B. 36, Bradford C.B. 17); Middlesex 53 (Willesden M.B. 28); Warwickshire 24 (Sutton Coldfield M.B. 10); Derbyshire 21 (Repton R.D. 21).

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported during the nine years 1943-51 are shown thus -----, the figures for 1952 thus ————. Except for the curves showing notifications in 1952, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

IMMOBILIZATION BY GYPSONA AFTER SKIN GRAFTING OPERATION

These illustrations and the brief details below are of an actual case where, after a skin grafting operation, a Gypsona plaster of Paris cast was used to immobilize the patient.

In such a case Gypsona is particularly convenient. The bandages are ready for immediate use and are quick setting. Being evenly impregnated with a uniform content of plaster of Paris, they can be quickly formed into a strong but light cast — with a minimum of disturbance to the patient in the post-operative condition.

CASE HISTORY: Boy received a burn covering 16% of body surface. Plasma transfusion started and the burn dressed with penicillin cream.

There was almost complete skin destruction, and a fortnight later early granulations were visible through separating slough. Under general anaesthetic, these were stripped off leaving a clean raw area. This was covered with split skin grafts which were fixed with crepe pressure dressings. The child was immobilized in a Gypsona cast.

A week later, the cast was removed. 100% take of grafts. Tulle gras dressings applied. Three weeks later the boy was discharged home, walking satisfactorily.

GYPSONA, ELASTOCREPE and JELONET are made by T. J. Smith & Nephew Limited, Hull. Outside the British Commonwealth, Elastocrepe is known as Tensocrepe.

OTHER SMITH & NEPHEW PRODUCTS USED IN THIS TECHNIQUE

JELONET (Tulle gras) is an open mesh gauze dressing impregnated with medicated soft paraffin containing 1.225% Balsam of Peru. Its non-adherent properties prevent dressing trauma, making it particularly suitable for wound areas encountered in skin grafting operations.

ELASTOCREPE is Elastoplast cloth without the adhesive spread. It therefore maintains uniform tension when stretched for long periods, keeping the pressure dressing firm throughout the immobilization.

Gypsona

PLASTER OF PARIS BANDAGES

Full details are available on request to the Medical Division, T. J. Smith & Nephew Ltd., Hull.

For Nasal Congestion

'Neophryn' (active principle a sympathomimetic substance) is an ideal local application for nasal congestion—particularly in children. It causes no impairment of ciliary function, no local irritation and no secondary congestion.

Three or four drops are instilled into each nostril. The patient should lie flat with chin raised and neck fully extended, and maintain this position for two minutes.

Medical Literature available on request.

Neophryn is known overseas as Neosynephrine.

The complete answer for macrocytic anæmias

Clinical experience over a decade has established that the administration of Anahæmin constitutes the most effective form of treatment for pernicious anæmia.

Anahæmin produces, with small and comparatively infrequent doses, a prompt and satisfactory erythropoiesis in patients in relapse, it ensures the maintenance of a normal erythrocyte level in patients in remission and is effective in preventing the onset of subacute combined degeneration of the cord.

Anahæmin has also been found to be of value in the treatment of herpes zoster and post-herpetic neuralgia. The recommended dosage is 2 ml. followed by 1 ml. on subsequent days until relief is obtained.

Diphtheria Immunization

The immunizations of children under 5 years of age against diphtheria were 141,000 fewer in 1950 than in 1949. An inquiry was carried out for the Ministry of Health by the Social Survey and a summary published in the February issue of the *Monthly Bulletin of the Ministry of Health and the Public Health Laboratory Service*. In a sample of 1,254 children between the ages of 6 months and 5 years there were 26% who had not been immunized and a further 5% who had not completed the immunization course. Of the children between 6 and 12 months of age 72% had not been immunized. The number with completed immunization rose steadily with age to 82% at 4-5 years.

67% of the children had been inoculated in the arm, the left arm being the most popular site. Inoculation in the

arm caused the least discomfort. Soreness in the arm was reported by 11% of the mothers, compared with 31% who reported soreness following inoculation in the legs.

It appears from this report that the success of the campaign in almost eliminating diphtheria has led to some apathy among mothers who have lost their fear of diphtheria as a deadly illness. If diphtheria is to be kept at its present low incidence an adequate level of immunization in the population must be maintained.

Tuberculosis Mortality in Scotland

The Registrar-General for Scotland in his annual report for 1949 states that the death rate from all forms of tuberculosis was 67 per 100,000 for 1949. This is the lowest rate ever recorded in Scotland, being 8 below the rate for 1948 and 2 below the previous lowest level recorded in 1938. The death rate from respiratory tuberculosis was 60 per 100,000 and was 6 below the level of 1948 but still above the level of the immediate pre-war years. The lowest death rate from respiratory tuberculosis was 52 per 100,000, which was recorded in 1938.

Road Accidents in 1951

Casualties on the roads in December, although fewer than in November, were the heaviest recorded in this month for 10 years. The total was 18,187, including 521 killed and 4,578 seriously injured. Over one-sixth of them occurred on the last four week-days before Christmas. Casualties reached their peak on Christmas Eve, with a total for this one day of 1,065, including 24 killed.

Casualties in 1951, the first complete year since petrol rationing was abolished, totalled 216,493, including 5,250 killed and 52,369 seriously injured. In 1950, when there were seven months without petrol restrictions, the killed numbered 5,012, seriously injured 48,652, and slightly injured 147,661, making a total of 201,325. The 1951 total was, however, 16,866 fewer than in 1938, when casualties totalled 233,359, including 6,648 killed.

Week Ending February 16

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,481, whooping-cough 2,550, diphtheria 48, measles 4,980, acute pneumonia 1,175, acute poliomyelitis 20, dysentery 636, paratyphoid fever 3, typhoid fever 3.

Medical News

Mixed Bag.—The March issue of *Family Doctor*, out on February 28 at 1s. 6d., contains a long article giving a sensible picture of what it is like to be a nurse, which would be useful reading to any girl thinking of going in for nursing; advice on dandruff; how to nurse children at home; and useful recipes to tempt the invalid's appetite, as well as advice on breast-feeding, growing deafness, influenza, and many other matters: altogether a very varied issue.

"Alcoholism: A Social Problem" is the title of a booklet just issued by the Advisory Council on Alcoholism, setting out a new policy of attack on alcoholism as an illness and a new approach to its treatment. The World Health Organization recently published figures showing that there are 86,000 chronic alcoholics in England and Wales, and of these a large number are permanently unemployed, many in prison and mental hospitals. The council proposes to tackle the problem from the educational angle, holding that nothing can be done as long as the general public remains ignorant of the true facts. Alcoholism is a disease, the alcoholic a sick person who can be helped and is worth helping. This is a public-health problem and therefore a public responsibility, and the council seeks the support of

the public in its campaign. The chairman is Dr. T. A. Munro, and members of the council, who represent many different sections of the community, include Sir Frederick Bartlett, Dr. J. A. Hobson, the Reverend Canon J. T. Hughes, and Mrs. Marty Mann, chairman and executive director of the National Committee on Alcoholism, New York, who is acting as consultant. Full information about the work of the council may be obtained from the secretary, Mr. Forbes Cheston, 99, South Hill Park, London, N.W.3.

Royal Statistical Society Prize.—The council of the Society offers the Frances Wood Memorial Prize, value £30, for competition in 1952. The object of the prize is to encourage young investigators, and it is offered for the best investigation, on statistical lines, of any problem bearing directly or indirectly upon the economic or social conditions of the people. Such investigations might, for example, concern housing, food production and distribution, health and nutrition, conditions of work, output, incomes and expenditure, education, and old age. Competitors must be under the age of 30 on January 1, 1952, but need not be Fellows of the Society. Entries, which must be printed or typed on foolscap or quarto paper (diagrams may be hand-drawn), must be sent to the honorary secretaries of the Royal Statistical Society (from whom full details may be obtained), 4, Portugal Street, W.C.2, not later than December 31.

Services' Dental Congress Subscriptions.—At a meeting of the organizing committee of the XIth International Dental Congress held on January 26, the question of reduced subscriptions for members of the armed Forces attending the congress (to be held in London July 19 to 26) was discussed. It was decided that any officer holding the rank of major or below, or its equivalent rank, in the armed Forces in Europe and the United Kingdom would be admitted to active membership of the congress at the reduced subscription of £2 15s., provided an enrolment form is presented endorsed by a senior dental officer in his Service and that the officer concerned attends the congress in uniform. All inquiries about the congress should be addressed to Mr. G. H. Leatherman, 13, Hill Street, London, W.1.

World Tour for W.H.O. Director-General.—Dr. Brock Chisholm is to make a 23,000-mile trip which will take him to Pakistan, India, Ceylon, Singapore, Thailand, the Philippines, Hong Kong, Japan, Canada, the United States, and the United Kingdom. He is expected back in Geneva on April 25. He will discuss international health programmes with the national administrations concerned, inspect projects undertaken with W.H.O. aid, and discuss plans for future operations. While in the United Kingdom he will attend the health congress of the Royal Sanitary Institute at Margate in April, and will give an address at London University on April 24.

Middle East Visit.—Professor F. A. R. Stammers, of Birmingham, is about to visit Bagdad, Cyprus, and Khartum under the joint auspices of the British Council and British Medical Association. In Bagdad he will attend the annual general meeting of the Middle East Branch of the B.M.A. on March 3, 4, and 5. He will be in Cyprus March 6-21, and will spend March 22-26 in Khartum, lecturing and visiting hospitals.

Emergency Bed Service: Applications and Admissions.—During the seven days ending February 25 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,138, of whom 88.84% were admitted.

COMING EVENTS

Blood Transfusion Conference.—An international conference will be held in London at the British Standards Institution, Victoria Street, S.W.1, from March 3 to 5. The object of the conference is to seek the international standardization of blood transfusion equipment, and full details may be obtained from the secretary of the institute (telephone Abbey 3333).

St. John Ambulance Brigade Conference.—The surgeons of the St. John Ambulance Brigade will hold their Northern surgeons' conference at the Spa Hotel, Buxton, on April 26 and 27. Sir Harry Platt, Mr. R. Guy Pulvertaft, and Major Harold Stewart will speak. Further information can be obtained on application to the conference secretary, St. John Ambulance Brigade, 8, Grosvenor Crescent, S.W.1.

Chesterfield Medal Examination.—The Chesterfield Medal examination in dermatology, 1952, will be held at the Institute of Dermatology, St. John's Hospital for Diseases of the Skin, Leicester Square, London, W.C.2, on Monday, Tuesday, and Wednesday, April 7 to 9. The examination will include papers on general dermatology and pathology, an essay, and an oral examination. Particulars may be obtained on application to the secretary.

Week-end Seminar for M.O.H.s.—A residential week-end seminar for medical officers of health and health education officers will be held at Southlands College, Wimbledon Park Side, London, from April 18 to 22. The subject of the course will be health education for mental health, and will cost £4 4s. Full details may be obtained from the medical director of the Central Council for Health Education, Tavistock House, Tavistock Square, W.C.1.

C.M.F./M.E.F. Physicians' Dinner.—The C.M.F./M.E.F. physicians' seventh reunion dinner will be held at Grosvenor House on Saturday, April 5, with Dr. E. R. Boland in the chair. Inquiries should be addressed to Dr. A. Willcox, 66, Harley Street, London, W.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Friday

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, London, W.—February 29, 7.30 p.m., general meeting. "*Prostitution and Venereal Diseases in Uruguay*," by Senorita Gloria Lanza. (Senorita Lanza will speak instead of Dr. F. R. Curtis.)

Monday

INSTITUTE OF NEUROLOGY, National Hospital, Queen Square, London, W.C.—March 3, 5 p.m., "*Neurological Manifestations of Porphyrinuria*," Guest Lecture by Dr. Raymond Garcin.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—March 3, 8.30 p.m., "*The Surgery of the Heart and Great Vessels*," Third Lettsomian Lecture by Mr. R. C. Brock.

PHARMACEUTICAL SOCIETY, 17, Bloomsbury Square, London, W.C.—March 3, 7.30 p.m., "*The Use of Films in Science Teaching*," by Dr. B. Stanford.

Tuesday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C.—March 4, 5.30 p.m., "*The Effects of Haemorrhage on the Peripheral Circulation in Man*," by Dr. O. G. Edholm.

CHADWICK TRUST.—At Sir Edward Meyerstein Lecture Theatre, Westminster Medical School, 17, Horseferry Road, London, S.W.—March 4, 5.30 p.m., "*The Prevention of Dental Caries by the Administration of Fluorine in Public Water Supplies*," Chadwick Public Lecture by Lieutenant-Colonel E. F. W. Mackenzie.

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—March 4, 5.30 p.m., "*Antibiotics in Skin Diseases*," by Dr. F. R. Bettley.

WEST END HOSPITAL FOR NERVOUS DISEASES, 40, Marylebone Lane, London, W.—March 4, 5.30 p.m., neurological demonstration by Dr. G. Parsons-Smith.

Wednesday

BIRMINGHAM MEDICAL INSTITUTE: MIDLAND MEDICAL SOCIETY.—At 154, Great Charles Street, Birmingham, March 5, "*Some Medical and Actuarial Aspects of Life Assurance*," by Dr. E. Bulmer and Mr. B. Priestman.

CAMBRIDGE UNIVERSITY.—At Department of Physical Chemistry, Free School Lane, Cambridge, March 5, 12 noon, "*Some Aspects of the Physical Chemistry of Amino-acids, Peptides, and Proteins*," by Professor John T. Edsall (Harvard University).

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—March 5, 5.30 p.m., "*The Chemistry and Bacteriology of Antibiotics*," by Dr. J. O. Oliver.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C.—March 5, 4.30 for 5 p.m., "*Non-gonococcal Urethritis*," by Dr. A. H. Harkness.

OXFORD UNIVERSITY.—At Radcliffe Infirmary, Maternity Department Lecture Theatre, Oxford, March 5, 5 p.m., "Some Old and New Views on Localization of Function in the Cerebral Cortex," Litchfield Lecture by Dr. F. M. R. Walshe, F.R.S.
ROYAL MICROSCOPICAL SOCIETY, Tavistock House South, Tavistock Square, London, W.C.—March 5, 6 p.m., "Some Techniques of Modern Enzyme Histochemistry and Their Application," by Dr. A. G. Everson Pearse.

Thursday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., March 6, 5.30 p.m., "Environmental Factors in Work," by Professor G. P. Crowden.

EPSOM AND SUTTON INTER-HOSPITAL PSYCHIATRIC ASSOCIATION.—At St. Ebba's Hospital, Epsom, March 6, 8 p.m., clinical meeting. Case demonstrations by Dr. J. C. Batt. Papers, "Treatment of Juvenile Psychiatric Disorders," by Dr. D. E. Sands; "Some Aspects of the E.E.G. in Juvenile Psychiatric Cases," by Dr. G. H. A. Chamberlain; "Factors Contributing to the Necessity of Prolonged Psychiatric Treatment," by Dr. W. McIntyre.

FACULTY OF HOMOEOPATHY.—At Royal London Homoeopathic Hospital, Great Ormond Street, London, W.C., March 6, 5 p.m., "Vomiting in Infancy and Childhood," address by Dr. D. M. Foubister.

●INSTITUTE OF CHILD HEALTH, Hospital for Sick Children, Great Ormond Street, London, W.C.—March 6, 5 p.m., "Modern Orthopaedic Principles," by Mr. H. J. Seddon.

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—March 6, 5.30 p.m., "Histopathology of Ecto- and Mesodermal Naevi," by Dr. H. Haber.

LIVERPOOL MEDICAL INSTITUTION, 114, Mount Pleasant, Liverpool.—March 6, 4.30 p.m., joint meeting with Manchester Medical Society. "Opportunities for Research in General Practice," by Professor Robert Platt; "Art in Paediatrics," by Professor Wilfrid Gaisford.

LONDON UNIVERSITY.—At Wright-Fleming Institute Lecture Theatre, St. Mary's Hospital Medical School, Paddington, W., March 6, 5 p.m., "The Cerebellum and its Connexions in the Light of Recent Investigations," Special University Lecture in Human Anatomy and Morphology by Professor Jan Jansen (Oslo University).

MEDICAL SOCIETY OF LONDON.—At Claridges, Brook Street, London, W., March 6, annual dinner.

●MOTHERS' CLINIC, 108, Whitfield Street, London, W.—March 6, 2.30 p.m., lecture and demonstration (on living models) on contraceptive technique by Marie C. Stopes.

ROYAL SANITARY INSTITUTE.—At Mansion House, Doncaster, March 6, 10 a.m., papers: "Co-ordination Within the Welfare Service," by Dr. Llywelyn Roberts; "Recent Advances in Insecticides," by Mr. I. A. Mackay, B.Sc. Afternoon visits.

ROYAL SOCIETY, Burlington House, Piccadilly, London, W.—March 6, 4.30 p.m., "The Rowett Research Institute," by Dr. D. P. Cuthbertson.

ST. ANDREWS UNIVERSITY.—At Lecture Theatre, Materia Medica Department, Medical School, Small's Wynd, Dundee, March 6, 5 p.m., "Problems Connected with Old Age," by Dr. A. G. Anderson.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—March 6, 4.30 p.m., lecture-demonstration in neurology by Dr. D. Williams.

UNIVERSITY COLLEGE, Physiology Theatre, Gower Street, London, W.C.—March 6, 4.45 p.m., "Mitochondria and Biological Oxidations and Phosphorylations," by Dr. A. L. Lehninger (Chicago).

Friday

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—March 7, 5.30 p.m., "Common Skin Diseases in Children," clinical demonstration by Dr. R. T. Brain.

●INSTITUTE OF DISEASES OF THE CHEST AND INSTITUTE OF CARDIOLOGY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., March 7, 5.30 p.m., "Medical Aspects of Rheumatic Heart Disease," by Dr. Graham Hayward.

OXFORD UNIVERSITY.—At Magdalen College, Oxford, March 7, 5 p.m., "The Neurophysiological Basis of Mind," Waynflete Lecture by Professor J. C. Eccles, F.R.S.

UNIVERSITY COLLEGE, Physiology Theatre, Gower Street, London, W.C.—March 7, 5.30 p.m., "Cell Physiology and Pharmacology—The Distinct Nuclear and Cytoplasmic Actions of Drugs," by Professor J. F. Danielli, D.Sc.

Saturday

BIRMINGHAM MEDICAL INSTITUTE: SECTION OF ODONTOLOGY.—At Medical School, Hospitals Centre, Selly Oak, Birmingham, March 8, clinical meeting.

BIRTHS, MARRIAGES, AND DEATHS**BIRTHS**

Brown.—On February 4, 1952, at the British Military Hospital, Singapore, to Marguerite, wife of Squadron Leader T. C. Brown, G.M., a son—Christopher.

Edwards.—On February 7, 1952, at Queen Charlotte's Hospital, London, W., to Hetty, wife of Dr. Errol M. Edwards a son—Jonathan.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Pregnancy Tests

Q.—Have there been any recent improvements in laboratory tests for pregnancy? Which is the earliest to give a reliable answer? Is anything known about a test in which serum expressed from the breast is injected subcutaneously into the forearm?

A.—The original Aschheim-Zondek test, which uses ovulation in the immature female mouse as its end point, is still one of the most accurate pregnancy diagnosis tests and probably is the earliest to give a reliable answer. All "improvements," therefore, have been intended to simplify the technique, reduce the time required to perform the test, or dispense with animals.

The Friedman test uses a single intravenous injection into a mature female rabbit (in place of several injections into several mice) and requires 24 to 48 hours as compared with five days. The Hogben test uses external ovulation in the South African clawed toad (*Xenopus laevis*) and requires about 24 hours. The male South American toad (*Bufo arenarum* Hensel), North American leopard frog (*Rana pipiens*), and edible frog (*Rana esculenta*) respond to injection of pregnancy urine within three hours by expelling spermatozoa into the cloacal urine, whence they are easily removed and observed beneath the microscope. Chemical tests (such as pregnanediol assay) on the patient's urine are less reliable than animal tests. Properly recorded basal temperatures taken first thing every morning also give reliable answers very early in pregnancy (within three weeks of ovulation—ordinarily one week after the expected onset of the "missed" period).

The colostrum test was described by Falls, Freda, and Cohen (1941); it was claimed that the intradermal injection of 0.02 ml. of a solution consisting of equal parts of human colostrum and physiological saline produced no reaction in pregnant women, but a typical allergic response (flare and wheal) within half an hour in non-pregnant women. In the original publication there were 98% correct answers in 265 pregnant women and 96% correct answers in 113 non-pregnant women. Few subsequent reports have confirmed these findings and most—for example, Pulver and Posner, 1942; Allen and Donaldson, 1943—indicate the test to be quite unreliable. There do not seem to have been any reports since 1945, and it may therefore be concluded that no further interest in the test remains.

Insulin-resistance and Schizophrenia

Q.—What determines the size of the dose of insulin in insulin coma therapy? Does the dose bear any relationship to the severity of the mental illness?

A.—The dose of insulin required to produce coma varies very much from case to case. In schizophrenics it is generally higher than in normal persons or patients suffering from other conditions, 300 units or more being quite commonly required. Insulin-resistance is thought to be aetiologically related to the disease, and many clinicians are convinced that patients with a high resistance to insulin have a worse prognosis. Little is known for sure on this subject, which is theoretically important.

Mitigation of Assault

Q.—In a case of assault, to what extent is the presence of a pre-existing abnormality which is liable to make fracture of a bone easier than usual a defence in law? For example, as a result of a blow a fracture occurred of the body of the mandible at the site of a dental cyst.

A.—The fact that a person was suffering from some abnormality which would render him more liable to serious injury if he should be the victim of assault is no defence in law, the assailant being liable for all the consequences of his act. If, however, a condition such as that described were proved to be present, it would no doubt be taken into consideration in deciding the penalty. Therefore, though no defence in law is available, a plea of mitigation would no doubt be successful.

Disseminated Sclerosis

Q.—(1) Is a diagnosis of disseminated sclerosis tenable if no physical signs are detectable other than "doubtful blurring" of the nasal margin of one optic disk six years after a supposed attack of optic neuritis? There have been no suspicious symptoms during this period. (2) Is there a hereditary factor in disseminated sclerosis? (3) Does pregnancy precipitate or aggravate disseminated sclerosis?

A.—(1) Disseminated sclerosis is generally considered to be the most common cause of unilateral retrobulbar neuritis occurring in Great Britain. Blurring of the nasal margin of an optic disk is not a frequent sequel of retrobulbar neuritis, and on the slight facts given in the question it would be unwise to make a certain diagnosis of disseminated sclerosis.

(2) There is no apparent hereditary factor in the majority of cases of the disease, but familial cases do occasionally occur. In a recent series of 310 consecutive cases (*Brain*, 1951, 74, 191) a positive family history was recorded in 6.5%, which was considered to be significantly higher than that expected on the basis of a random distribution of the disease.

(3) It is a widely held opinion that a relapse or aggravation of existing symptoms of disseminated sclerosis commonly follows parturition, and individual cases to support this opinion could be quoted by most neurologists, but in a comprehensive study of the prognosis in 810 patients with the disease in Sweden (*Acta med. scand.*, 1949, 133, Suppl., 222) the author could find no statistical evidence to show that pregnancy or parturition alters the course of the disease.

Alcohol for Angina

Q.—Is alcohol bad for hypertensive patients who occasionally suffer from anginal pains?

A.—In moderation, particularly amongst those accustomed to its use, alcohol cannot be regarded as harmful to hypertensive patients liable to angina pectoris. In point of fact, as long ago as 1768 Heberden, in his original description of angina entitled "Some Account of a Disorder of the Breast," noted "the relief afforded by wine and spirituous cordials"—an observation which has been confirmed by many sufferers. Some claim that they obtain almost as much relief, though not so promptly, from a sip of whisky or brandy as they do from nitrites. As a vasodilator it is possible that alcohol thereby relieves or prevents in some measure the myocardial ischaemia responsible for the anginal attack by increasing local blood flow. Comfort is sometimes attributed to the prompt carminative action of the stronger spirits, such as liqueurs, taken undiluted after a meal, when anginal attacks are particularly prone to occur. It is also claimed that whisky before retiring reduces the liability to nocturnal attacks. In so serious a disorder fears of habituation are seldom warranted, but nevertheless, were it not for the risk of the corruption of his patient, the practitioner would no doubt be tempted to order alcohol more

generously for sufferers from obliterative vascular disease. Unless the hypertensive patient is overweight or presents definite evidence of chronic alcoholism, there is at least no justification for countermanding alcohol amongst those afflicted with angina.

Idiosyncrasy to Morphine

Q.—How common is idiosyncrasy to morphine? What are its manifestations? How specific is it? A patient under my care with a coronary thrombosis who was given morphine gr. $\frac{1}{2}$ (11 mg.) developed respiratory depression. Was this due to an idiosyncrasy to morphine?

A.—The idea of idiosyncrasy is slowly giving place to the conception that there is a wide variation in sensitivity to all drugs. According to this view the pharmacopoeial dose of morphine will cause an excessive response in a small percentage of persons—perhaps in much less than 1%. The excessive response will be shown by the evidence of the usual toxic effects of morphine, which are vomiting, respiratory depression, and perhaps intense itching. The patient who developed respiratory depression after morphine gr. $\frac{1}{2}$ was one of these more sensitive individuals.

Mild Aperient for the Elderly

Q.—What mild aperient for regular use would you recommend for a man of 83 who has great trouble with his bowels and is nauseated by liquid paraffin?

A.—A simple anthracene-group laxative would seem suitable for such a case, to be taken every night in the smallest quantity which will ensure a soft, formed, regular motion. I suggest the liquid extract of cascara sagrada, the elixir of cascara sagrada, the syrup of senna, or the concentrated infusion of senna. These are all B.P. preparations. The minimum dose necessary will have to be found by trial and error. The average dose of any of these preparations is from 2 to 8 ml. (30 to 120 min.).

NOTES AND COMMENTS

Strained Eyes.—Dr. A. VICKERS (Worcester) writes: The answer under the above heading ("Any Questions?" January 26, p. 229) contains the following statement: "The misuse of the eyes from working in bad light . . . may have both general and local results". . . Probably few people spend more of their time working in indifferent lighting, peering hopefully at a dim moving image often well within 10 in. (25.4 cm.) of the eyes, than many diagnostic radiologists. Surely it is established that poor lighting does not of itself contribute in any way to ill health, either general or local, provided that one knows how to use one's eyes without straining, "straining" in this context being defined as conscious and subconscious endeavour to see that which is not visible.

OUR EXPERT writes: I am not in agreement with Dr. Vickers. Unfortunately not everyone working in a dim light can eliminate altogether "conscious and subconscious endeavour to see that which is not visible." Apart from the specific example he gives, the tendency in many cases is to crouch and to get the eyes too close to the work. If persisted in, these positional errors may lead to postural and local troubles, especially in the young.

AUSTRALIA'S NATIONAL HEALTH SERVICE

BY

J. G. HUNTER, M.B., Ch.M.

General Secretary, Federal Council of the B.M.A. in Australia

PART I. ATTEMPTS TO NATIONALIZE MEDICINE

Standstill and advance in the development of national health services in Australia may be summarized as in two phases.

After six years of resistance the medical profession in Australia assured its freedom against the then (Labour-Socialist) Government, whose admitted "ultimate object," in its scheme for free medical and pharmaceutical benefits, was complete nationalization of medical services.

The present (Liberal-Country Party) Government intends no interference with the freedom of doctors. It has obtained the profession's full co-operation in planning a national health service. Elements of the programme already carried into effect include: free treatment and free medicine for pensioners and their dependants; and, for the entire community, free "life-saving and disease-preventing" drugs.

Ultior Objective

It may be valuable to present an outline of the first phase, since this illustrates the manner in which a scheme for social services might be utilized to attempt an ulterior objective—that of nationalization.

In this instance, resort was had to a device which the High Court of Australia found to be unconstitutional, as amounting to peacetime "civil conscription" of doctors. (Australia has a written constitution which permits no such form of conscription.) The method proposed by the then Government, led by the late Rt. Hon. J. B. Chifley, was to make it impossible for the individual doctor to earn a livelihood

unless he should accept Government control in the prescribing of medicines for his patients. Incidentally, if the British Medical Association in Australia had not fought on this issue, and won, a way would have been opened to State regimentation of any group in the community.

Although the Federal and six State Parliaments in Australia had made many experiments in social legislation, including some not elsewhere tried, no comprehensive scheme for free medical services and pharmaceutical benefits was initiated until 1947. To understand the constitutional obstacles to any such scheme it is necessary to recall that the Federal Parliament cannot legislate in a manner which would be inconsistent with any definite head of power written into the Constitution itself. The subject-matters of its powers, though the range is wide, are precisely defined. Its powers are those only which the States, at Federation or since, have surrendered or which the people by referendum have given to the Commonwealth. Accordingly, the validity of any legislative Act of the Federal Parliament can be challenged before the High Court. Here is an essential difference between the constitutional system of the Commonwealth and that of Great Britain, where Parliament possesses supreme and sovereign power.

Prescription from a Formulary

In 1944 the Federal (Labour) Government introduced a Pharmaceutical Benefits Act, which was passed by Parliament in the belief that authority to do so was contained in the financial and incidental powers of the Constitution.

A basic provision was that medicines, if the patient were to receive them free, must be prescribed from a Government *Formulary* of drugs. This would place the doctor in the dilemma of having either to confine his choice to the standardized prescriptions in the *Formulary* or to prescribe otherwise if his judgment required it—in which case he might incur the displeasure of his patient, who would be taxed to pay for the benefit.

Adjudication March 10

Mr. Justice Danckwerts has fixed March 10 as the date when adjudication begins. The two sides have exchanged their statements of the case (see page 77). The G.M.S. Committee answers critics (see page 77).

The Shilling on Prescriptions

The G.M.S. Committee seeks to protect 4,000 dispensing doctors from serving as Government collectors and from losing financially. It has asked for an interview with the Minister (see page 76).

Strong exception was taken by the medical profession to the provisions of the Act, and its attitude was very clearly stated by Sir Henry Newland, the then President of the Federal Council of the British Medical Association, in a letter to the Minister for Health. He said:

"I have been requested to convey to you with all respect the opinion of the Federal Council that rigid adherence to a formulary, and all the more if enforced by contract, violates the first great principle of medical practice—namely, that whatever the organization, the doctors taking part must remain free to direct their clinical knowledge and personal skill for the benefit of their patients in the way in which they feel to be best. The Federal Council holds that the medical profession, in the interests of the public weal, must retain the priceless asset of individual freedom and enterprise. On this principle, the Federal Council can make no compromise."

In the difficult few years that followed there was no compromise whatever by the medical profession on the issue of freedom. The measure was nullified when the Medical Society of Victoria, applying through the State Government to the High Court, obtained a declaration that the Act was invalid.

Following this defeat the Federal Government decided in 1946 to ask the people, by the method of a referendum, for an extension of powers. The referendum, which was approved, was in these terms: that the Commonwealth Parliament might make laws with respect to "the provision of maternity allowances, widows' pensions, child endowment, unemployment, pharmaceutical, sickness, and hospital benefits, medical and dental services (but not so as to authorize any form of civil conscription), benefits to students, and family allowances."

The decision of the people, who at the same time returned Mr. Chifley's Government with a substantial majority, seemed to put beyond doubt the power to establish medical, pharmaceutical, and dental services, free to all, which the Government had promised before the election. Long negotiations followed between the Minister for Health and the Federal Council of the B.M.A. on various features of the proposed scheme for free national health services. The Minister offered to drop sections of the 1944 Act which imposed penalties on doctors. There was discussion also of a plan submitted by the B.M.A. as an alternative to compulsory use of the *Formulary*, the plan later adopted by the Menzies Government—that is, the provision of the costly life-saving and disease-preventing drugs.

But on decisions made by the Cabinet the new Pharmaceutical Benefits Bill, when presented to Parliament, repeated the main objectionable provisions of the 1944 Act. In addition it included a new feature, one deeply resented by the medical profession. The penalty clause, which appeared in the body of the 1944 Act, and so was subject to open criticism and amendment if desirable, was replaced by a clause conferring on the Minister power to determine offences and penalties by simple regulation. Doctors feared that under this arbitrary power they might be oppressed by burdensome penalties or vexatious controls.

The Bill, passed by Parliament with extraordinary haste, received the Royal Assent on June 12, 1947. The profession's fears were justified by the nature of regulations made under the Act and gazetted in May, 1948.

Proposed Free Service

Meanwhile the Minister had conferred with the Federal Council of the Association on the subject of a proposed complete national medical service, free to all, but paid for out of social services taxation. The Government contemplated some form of direct contract between itself and doctors co-operating in the scheme; the method of payment might be fee-for-service, capitation, or salary, or a combination of these. Ministerial control of the health service would be insisted on. In reply, the Federal Council presented to the Minister a constructive statement of policy on national medical services. Essentials of this were: that the role of the Commonwealth Government should be to

supply capital expenditure; that any general medical service should be controlled by a non-Ministerial body in which doctors would form a majority; and that there should be free choice of doctor, payment at fee-for-service, and preservation of the contract between patient and doctor. There should be no contract between the doctor and the Government.

These were principal matters discussed at a conference held in July, 1947, between the Association and the Government on a national medical service. In retrospect, the occasion seems significant mainly because of a Ministerial remark which, when made public later, was to alert not only the doctors but all other citizens who would oppose nationalization of medical practice.

Having been asked repeatedly if the ultimate object of the Government's policy was the elimination of private medical practice, the Minister replied: "That is so. There is no dispute as to that."

Once aware of the ultimate object, the doctors closed their ranks. They were confident that their resistance would have the support of a large majority of the people. Indeed, the support which patients gave to their doctors was the most pleasing and heartening aspect of the dispute with the Government. But to the Government the practically complete silence of the public, in spite of being deprived of benefits for which they were being taxed, was most disconcerting. At this time Acts had been passed, or were contemplated, to nationalize banks, airlines, and shipping. Insurance was threatened with a like fate, and even the Press had become apprehensive of Government control.

When regulations under the Pharmaceutical Benefits Act were proclaimed in May, 1948, it was seen that the restrictive nature of the Act itself was aggravated by the substance of certain of the regulations. One (No. 34) introduced a novel method of invading the freedom of the subject. It was the Government's stated intention to deliver at every doctor's address a copy of the Government *Formulary*, a copy of rules for prescribing, and prescription forms. Regulation 34 authorized the Director-General of Health to call on the doctor, if he so desired and without warning, to deliver up these documents, in default of which he might be fined £50. Such was the spirit of these regulations. (Presumably it was feared that the documents would be used as waste paper, which indeed they later became.) The Association, having obtained counsel's opinion, advised its members to refuse delivery. Within two weeks the Act came into operation (on June 1), and immediately it was apparent that the scheme could not be made to work. Approximately 98% of doctors refused to accept State control through the *Formulary* and official prescription forms. The highest figure which the Government could give for those co-operating under the Act was 157 out of 7,000 practising doctors. Of doctors in private practice probably not more than 70 co-operated at any time.

Failure of the scheme, and the resulting loss of Government prestige, led to postponement of the National Health Service Bill, which did not reach Parliament until the end of 1948, and then only in the form of an enabling Bill, rushed through Parliament in a few hours right at the end of a session. In the debate, the Prime Minister, the late Rt. Hon. J. B. Chifley, used words which helped to strengthen the ever-growing opposition to the Government's proposals. Referring to the records to be kept by doctors, he said, "All that the doctor will be asked to do is to furnish a return showing the people he has attended and what they have been attended for."

Resistance to Nationalization

It followed that the issue of nationalization would be decided on the Pharmaceutical Benefits Act—or at the election due at the end of 1949. As the doctors continued to resist month after month (while subjected to attacks in Parliament and outside it by members of the party in power), the Government was driven gradually to the resort

of compulsion. Leaders of the profession could hardly repress the hope that the Government might in some way attempt conscription of the doctors' services. Here one should recall the safeguarding words of the referendum question: "But not so as to authorize any form of civil conscription." These words had been added to the text, with the Government's consent, by an amendment moved by the leader of the Opposition, the Rt. Hon. R. G. Menzies (now Prime Minister).

As the Federal Council of the Association was about to end its meeting in Melbourne, during March, 1949, it was informed by telephone message from Canberra that the Government was just then introducing an amendment to the Act. The effect of this amendment was that a doctor must not prescribe any medicament, compounded or not compounded, or any material or appliance, contained in the Government *Formulary*, except upon the Government prescription form. Immediately it was realized that this meant that doctors must either co-operate in the scheme or lose the right to prescribe lawfully a number of the medicaments used in their practice—for example, sulphonamides, antibiotics, adrenaline, etc.

The rest of the story may be told shortly. An "Independence Fund" was inaugurated to provide the means of challenging the amendment in the High Court, and later of presenting the doctors' case to the people by vigorous methods of publicity. On October 10, 1949, the Court gave its decision, holding by a four-to-two majority that the amendment was a form of civil conscription and therefore invalid.

Of the later publicity the most striking feature was the daily broadcasting by more than 500 family doctors throughout the length and breadth of Australia for a period of five weeks.

For the Government there was nothing left but to hope for a mandate, at the coming elections, to proceed with the socialization of medicine in Australia. In the result it met defeat, and gave place to a coalition Government led by Mr. Menzies.

PART II. HEALTH SCHEME WITHOUT SOCIALIZATION

During 1950 first steps were taken towards the objective of a national health scheme without socialization. The Minister for Health, Sir Earle Page, announced that the Government would avoid the mischiefs of State paternalism and would adopt, so far as possible, the principle of encouraging voluntary health insurance. Generally, its method would be to use its funds to amplify the cover against sickness provided by approved insurance organizations. Instead of indiscriminate State charity, made possible by burdensome taxation, there would be help for those willing and able to help themselves, with special aid for the minority who for various reasons could not meet the cost of adequate medical care.

In a speech to Parliament on November 2, 1950, the Minister said that the new health scheme would establish a partnership between the individual and the State. His own task was to initiate a programme of medical benefits and provide the necessary machinery free of red tape, of departmentalism, and of vitiating restrictions on professional standards. Instead of regimenting the professions, the Government had chosen the method of a working partnership. In many instances already proposals had come from doctors, chemists, or hospital managements. Rejecting the centralization common to all socialized schemes, the Government had chosen the policy of decentralization. "The doctor's surgery and the pharmacist's shop became the headquarters where decisions could be made."

"Our policy aims," the Minister said, "to improve the quality of medical services in its essential factors by stimulating individual and community effort. It makes the individual a partner of the Government, not its servant. One

outstanding fact that has emerged from various schemes of socialization of medicine is that Government control of medical treatment, especially the handing out of treatment for nothing, does not improve the standards of medical treatment or of national or individual health. The most that Government control has been able to do has been to retain the *status quo ante*. In most cases, however, there has come inevitably a steady deterioration of the morale of the people, loss of skill of the doctors, especially general practitioners, through the enormous wastage of time in filling in forms, and consequent degeneration of the health of the patients. There is already evidence that that was happening in Britain and New Zealand and, where it applied, was beginning to happen in Australia. The Government's aim is to maintain the continuous improvement in the health of the Australian people that the progress of the last 50 years shows."

Past Progress

Outlining that progress, Sir Earle Page drew attention to the great decline in mortality rates at all ages between 1901 and 1947 and the increased expectation of life. These results were an expression of the cumulative efforts of the medical profession on the whole health front during this period. Insistent advice and pressure of doctors in Australia, as in other countries, had ensured improvement in water supplies, in sanitation, and in immunization against infectious diseases. By the research of doctors new germs, new drugs, and new methods of treatment had been discovered. The result was seen in a remarkable improvement in national health.

"The Australian people," Sir Earle Page continued, "have asked themselves why, when they are getting such magnificent results from our present health system, they should discard that system and attempt to sail on the uncharted sea of nationalization of medicine."

"In all nationalization schemes there has been pressure to cover the whole field at once. This of itself has led to chaos, and does not ensure that the area of treatment most needing care receives priority. Our first task was to direct attention to that huge bare area of sickness which was not covered in the past, but which now must be specially treated by reason of modern progress with means that have become increasingly expensive. With this ideal, the Government aims to deal with the problem of national health in two stages: first, that covered by current expenditure; secondly, that dealing with capital expenditure. Both stages will be designed to ensure a progressive improvement in all phases of the healing art—from teaching and research through to actual practice and the training of medical graduates qualified to deal with all emergencies. Intimate contact and knowledge of the general practitioner of the history, constitution, life, and circumstances of the patient make the preservation of his opportunities to use to the full all modern improvements in knowledge and technique one of the most important factors in a national health scheme."

Existing health insurance agencies that had proved their value would be utilized to the greatest possible extent. The Minister emphasized that the willing co-operation of doctors, chemists, hospital managements, voluntary organizations, and insurance societies should be secured by leaving in their expert hands as much as possible of the administration and control of the scheme. The patient should be given a definite sense of personal and social responsibility. It was essential that the scheme should result in raising the level and standard of medical care and treatment; in building up, not undermining, the self-respect and morale of the people at large.

"Experience of the rest of the world in regard to health schemes indicates," the Minister declared, "that the most likely system to satisfy all these requirements is one of voluntary insurance. Voluntary insurance will prove as valuable against unpredictable sickness risks as it has with life, shipwreck, theft, and other risks. It may be argued that voluntary insurance cannot cover the whole possible field of sickness risk on an actuarially determined premium. The Government aims to give this full cover with a system of cash benefits added to the insurance benefits, for each item of sickness. The double benefit thus offered would meet roughly 80 to 90% of the cost of medical

treatment. The Government benefit would also be continued to the sick, for medical and hospital care, even after the ordinary insurance benefit expires."

Present Arrangements

Steps taken to date in putting the programme into effect may now be summarized. They have been, successively: the provision of free milk to schoolchildren; payment of increased allowances to sufferers from tuberculosis; free supply, on a doctor's prescription, of life-saving drugs to all persons requiring them; provision of free medical treatment and free medicine to pensioners and their dependants; and financial assistance to contributors to voluntary schemes for the provision of hospital benefits. Some details of these measures may here be given.

By arrangement with the State Governments, free milk up to a half-pint daily is provided for children below the age of 12 years attending public and private primary schools and recognized kindergartens, nursery schools, and creches. In places situated far from fresh milk supplies (as are many throughout the continent) powdered milk is kept to be made up for drinking.

A scheme of tuberculosis allowances was brought into operation on July 13, 1950. Rates at present payable to the main categories of sufferers are: £A8 5s. a week to a married man with a dependent wife; and £A5 a week to a sufferer without dependants, reducible to £A3 a week when the sufferer without dependants is accommodated in a hospital or tuberculosis institution free of charge. An allowance of £A5 a week, without reduction for free institutional accommodation and treatment, will be paid to a sufferer whose only dependant is a child or children under 16 years of age. There is also an allowance of 9s. a week each in respect of dependent children under the age of 16. This payment is additional to child endowment of 5s. a week for the first child and 10s. a week for each subsequent child under the age of 16.

A not ungenerous means test takes account of income only, not of property. Permissible income is £A4 a week (including wife's income) in the case of a married man with dependent wife, and £A2 a week for other categories. Allowances cease, however, when the earnings of a sufferer, entitled to the rate of £A8 5s., reach this figure.

The tuberculosis allowances scheme is designed to check the spread of infection by enabling sufferers to give up work and take treatment. It is in the interest not only of sufferers but of the rest of the community. This justifies the payment of higher allowances than other classes of invalid receive.

General Practitioner Treatment

The third measure, introduced on September 4, 1950, makes available, free to all citizens, life-saving and disease-preventing drugs on submission to any approved chemist of the prescription of a registered medical practitioner. There are no intermediaries between doctor, chemist, and patient. The Government, through the Department of Health, pays the chemist on production of the doctor's prescription. Prescriptions are handled by any chemist or dispensary selected by the patient.

Drugs cover treatment for those diseases which are responsible for most of the deaths in the community. They include all the sulphonamides, insulin, penicillin, streptomycin, chloramphenicol, "aureomycin," vaccines, and sera. Others will be added from time to time, as medical science advances. There is no means test. The list of drugs was drawn up by a Pharmaceutical Benefits Advisory Committee, nominated by the Federal Council of the B.M.A., and this committee advises the Minister for Health about new additions to the list. The list includes all known proprietary brands of listed drugs. An identifiable prescription form, the doctor's own form with the words "Pharmaceutical Benefits" imprinted on it, is used in duplicate.

The fourth step is the provision of free general practitioner medical treatment and free medicine (in addition to the life-saving drugs available to all citizens) for aged, invalid, and widowed pensioners and their dependants. Medical services are services such as are rendered by a general practitioner in his surgery or the patient's home and for which the practitioner normally charges a consultation or visiting fee. Names of participating doctors are furnished to the Department of Health by the B.M.A.

There is no contract between the individual doctor and the Government. By arrangement with the Federal Council of the Association, pensioners are charged concessional rates—at the moment 8s. a consultation and 10s. a visit, representing approximately 60% of private charges. The practitioner receives payment not from the patient but from the Government, on the authorization of the patient, who signs a voucher certifying that he has received service and requesting that payment be made directly to the medical practitioner on his or her behalf.

A medical practitioner providing medical services to pensioners may prescribe any drug in the *British Pharmacopoeia* and such additional drugs as may be from time to time prescribed by regulation or any combination of such drugs. At the request of the Minister for Health, a committee appointed by the Federal Council has prepared a formulary—the *Prescribers List*—for the guidance of medical practitioners in their prescribing. This committee also advises the Minister for Health in regard to the additional drugs to be prescribed by regulation.

The latest step is the provision of an additional benefit of 4s. a day to patients in private hospitals who are contributors to voluntary hospital contribution schemes providing a minimum benefit of 6s. a day. (The rate of contribution is 3d. a week for a single contributor, 6d. a week for a married contributor.) Under the Chifley regime the Commonwealth entered into an agreement with the six States to pay 6s., later 8s., a day in respect of every bed occupied in a public hospital provided that no means test was applied. The benefit was also available to patients who elected to go into private hospitals. The effect of the new regulation is that a patient in a private hospital who is a contributor to a voluntary hospital contribution scheme will receive 18s. a day—12s. from the Commonwealth and 6s. from the contribution scheme towards the cost of hospitalization.

Conclusion

As the next step in the national health service the Government intends to subsidize approved voluntary schemes providing medical benefits. This measure may be introduced later this year. In this the underlying principle of Australia's national health scheme will find expression—the encouragement of voluntary effort on the part of all who are able to insure against the costs of illness.

THE SHILLING ON PRESCRIPTIONS

CRITICISMS BY G.M.S. COMMITTEE

The scheme for imposing prescription charges is held by the G.M.S. Committee to be impracticable in many respects. While the political issues do not concern the Committee, the position of the dispensing doctors does. There are 4,000 of these—that is, about 20% of the general practitioners in the Health Service. Ten per cent. are paid on the tariff system and 90% on the capitation system.

At its meeting on February 21 (reported on page 77) the Committee agreed to ask for an interview with the Minister of Health to bring up the following points:

- (1) *The profession should have been consulted earlier.*
- (2) *The profession has alternative suggestions to offer: it wants discussion on the whole question of economies in the pharmaceutical field.*
- (3) *The rural doctor doing his own dispensing needs special consideration.*
- (4) *Hardship on certain types of patient must be avoided.*

As previously reported (*Supplement*, February 16, p. 61), the Committee has instructed its representatives "to press the Government to take such steps during the passage of legislation as will alleviate hardship to certain sections of the population and will ensure that the doctor is not required to play any part in the actual collection of the money." The Committee does not regard this scheme as the best way of saving money. Suggestions made at the meeting include raising the National Insurance contribution by, say, 2d. a week, and affixing stamps to prescriptions.

The Dispensing Doctor

The Committee condemns the scheme in that it makes the dispensing doctor an agent for collecting Government money. If the patient fails to pay, the doctor loses—not the Treasury. Several members emphasized the difficulties in rural areas, where the doctor sometimes sets out the medicines on a shelf and the patients later collect them; or the doctor sends the bottles off by bus. In these circumstances it would be difficult to collect the shillings and there would in any case be much extra clerical work.

There would be many bad debts, which could not be compensated for as in the old days by adjusting private fees. In England and Wales there is no Form E.C.10A, and doctors giving stock orders might be out of pocket.

Again, if 3s. 6d. per year per patient is to be deducted from the doctors' pay some doctors will have to prescribe more than they do now in order to recoup themselves. As a member pointed out, this arrangement, designed to save, would encourage extravagance. The Committee also feared that the numerous explanations dispensing doctors would have to give their patients might damage the doctor-patient relationship.

ADJUDICATION MARCH 10

EXCHANGE OF DOCUMENTS

Mr. Justice Danckwerts has fixed March 10 as the date when adjudication begins. In accordance with his instructions the General Medical Services Committee and the Ministry of Health have exchanged statements on the general practitioners' claim for higher remuneration.

The first meeting of the Working Party to discuss distribution of remuneration was held on February 26. The Working Party consists of representatives of the G.M.S. Committee and officials of the Ministry of Health.

The Working Party Agreement

In agreeing to set up this Working Party (*Supplement*, August 25, 1951, p. 69), the Committee accepted two provisos. These were: (1) It undertook to accept whatever decision may be reached following arbitration; (2) It accepted that an agreement satisfactory to both sides should be reached on a revised plan for distributing the central pool. Therefore actual payment of whatever sum is awarded is conditional on agreement in the Working Party. In this connexion the Committee gave an assurance at the time "that it would be the aim of its representatives . . . to work harmoniously with a desire to provide the best possible service for the public and make possible a better and happier atmosphere among the doctors who take part in it, but in the Committee's view the profession would feel rightly aggrieved if the award following arbitration were nullified by failure to agree in the Working Party upon a proper distribution of the pool."

The Committee, together with its counsel and expert advisers, continues to prepare the case. An account of this was given at its meeting on February 20 (see next column), where a speaker emphasized again the difference between bargaining with the Ministry and preparing a case to put before a judge in court.

THE APPROACHING ADJUDICATION

COMMITTEE'S STRAIGHT ANSWER TO CRITICISM

A full two-day meeting of the General Medical Services Committee was held at B.M.A. House, London, on February 20 and 21. The special business on the first day was to consider in detail a report by the Committee's representatives on the Working Party concerning the distribution of the Central Pool. Before this was embarked upon, however, the CHAIRMAN, Dr. Wand, made emphatic reference to what he described as uninformed criticism appearing in the correspondence columns of the *Journal* and elsewhere concerning supposed delay for which the Committee was held responsible in starting arrangements for the adjudication.

Dr. Wand referred in particular to a resolution from the Plymouth Division expressing "profound dissatisfaction" with the delay in bringing the case before the tribunal. A similar resolution had been passed by the West Middlesex Division. These attacks were very disturbing. He and some other members, who were all busy general practitioners, together with Dr. D. P. Stevenson, the secretary of the Committee, had sacrificed a great amount of time, by night as well as day, on Sundays as well as weekdays, in making preparations for an occasion which would be of the very greatest importance to the profession now and in the future. He reminded the Committee that only as a result of insistent pressure on the Government were they able to secure the services of a High Court judge as adjudicator, and what was not understood by their critics was that now that the judge had been appointed the timing was in his hands and in the hands of counsel. It was no easy task to give to counsel the proper background and to ensure that all the issues in their case were fully appreciated.

Dr. HOWIE WOOD said that the chairman and secretary had no need to justify themselves to the Committee. They all knew how hard they had worked. There were a small number of dissident members outside who were making the most of the difficulties. He thought that the substance of what the Chairman had just stated should appear in the *Journal* above all their signatures.

Dr. J. C. ARTHUR suggested that the criticism came from those who rarely turned up at a meeting, and when they did so found something which they thought was wrong and without further inquiry expressed their indignation. Dr. FRANK GRAY said that the critics did not appreciate the difference between negotiating with the Ministry and preparing the case for an adjudicator. To convince a judge who came new to the facts was a different problem from arguing with a Minister or his officers who were anxious to make a bargain.

Dr. TALBOT ROGERS said that as these resolutions came from Divisions they must go to Council, and he proposed that they be accompanied by a statement from the Committee on the lines of what the Chairman had said, together with a unanimous expression of the utmost confidence in and admiration for those who were bearing the burden of this work. This was seconded by Dr. A. B. DAVIES, who said that more progress had been made during the last six months than during the previous three years, and that no apologetic explanations were necessary. Dr. W. WOOLLEY said that the ill-informed criticism which was current in some quarters at present embarrassed the Working Party and might jeopardize the success of the doctors' case.

The action proposed by Dr. Rogers was agreed to unanimously.

The Committee spent almost the whole of the rest of the day in considering the instructions it should give to its representatives on the Working Party at the first meeting of the two sides arranged for February 26.

THE SHILLING ON PRESCRIPTIONS

On the second day of its meeting the Committee discussed at length the report of an interview which its representatives,

including members of the Rural Practices Subcommittee, had had with officers of the Ministry of Health on the proposed charge for prescriptions. It was stated that the officers had proved most unyielding and were not prepared to modify their present proposals.

On the method of collecting the levy the Ministry had stated that the charges received from patients would form part of the total remuneration of dispensing practitioners, and that whatever dispensing capitation fee was in operation when the charges were introduced would be adjusted accordingly. In 1950 the average number of prescription forms issued by prescribing doctors per patient was 3.5, which would point to a deduction of 3s. 6d., but in this respect the Ministry was prepared to hear what deduction the Committee would consider reasonable.

Mr. H. NOBLE, secretary of the National Pharmaceutical Union, and other members of that body attended by invitation during the discussion on this subject. Mr. Noble said that his union had not thought it within its province to consider the social and political aspects of the problem. At a conference of the union an amendment was moved, but rejected, that they should seek to transfer to the medical profession the responsibility for collecting the charge. In the operation of the scheme in rural areas, although some doctors in a spirit of good will might act as intermediaries, they did not expect members of the profession to do so. They had made representations to the Ministry that the best solution would be by way of a stamp to be affixed to the prescription, but he gathered that this was regarded by the Ministry as unworkable. His members were having an interview with the Ministry later that day.

Unsuccessful Tax Collectors

"Dr. D. P. STEVENSON, secretary of the Committee, said that in a number of letters received at Headquarters the Committee had been accused of adopting an unrealistic attitude in that they had not welcomed a scheme which would mean less work for the great majority of general practitioners. One part of the resolution passed by the Committee at its recent special meeting and published in the daily newspapers had been taken out of its context and misunderstanding had arisen. The obligation of the Committee embraced the interests of both rural and urban practitioners, minorities as well as majorities, and it was necessary that the profession be informed of the strong feeling that existed against turning a section of the profession into "unsuccessful tax collectors."

Strong exception was taken to this aspect of the Government's proposal by a number of members of the Committee, one of whom described it as not only tax collection but as "farming out." A rural practitioner, a member of the Committee, said that he and his partner had 3,500 on their dispensing list. If 3s. 6d. a year per patient was to be deducted, it meant that they would have to collect £612 a year from these patients. This worked out at 34 medicaments a day, which was rather more than were actually dispensed. The result of this proposal would be to encourage extravagance. This member urged that attention be paid to the Australian scheme whereby certain essential drugs on the list were free and everything else had to be paid for (see p. 73 for an account of this scheme).

Pharmacists' Point of View

In some further presentation of the pharmacists' point of view Mr. NOBLE pointed out that, apart from the rural-practice aspects of the problem, there were a number of other features of the proposal which did not commend themselves to his union. Under the existing regulations the pharmacist was required to supply whatever was ordered on the prescription form and to do so with reasonable promptness. Technically at least the pharmacist would break his terms of service if, having failed to obtain or knowing that he could not obtain, the payment of the

charge, he said, "I am not going to dispense the prescription." Therefore he would have to dispense knowing that in many cases he would not obtain the shilling. Pharmacists also had in mind the possibility of a considerable reduction in the number of prescriptions owing to a feeling in the minds of doctors that out of consideration for their patient's pockets they should not prescribe save under strict necessity. They also foresaw the possibility of "hidden prescribing," that is to say, prescribing for a number of individuals on the same form, or the prescription of medicaments to cover a long period. The classic example of this last was a prescription of sufficient barbiturate tablets on one form to provide treatment for five years. But it was not unusual for such prescriptions to cover three months, and there might be an increase of that practice.

In the course of general discussion one member pointed out that it was two years ago that the then Government proposed a shilling charge on prescriptions, and in the intervening time the department must surely have had every opportunity of working out a practicable scheme of collection. Another said that he did not believe that the result would be to reduce the work of general practitioners, for, especially since the National Health Service came in, an increasing number of people came to the doctor for consultation and did not ask for or obtain a prescription. To suppose that the number of items of work of the doctor was bound up with the number of prescriptions was nonsense.

The answer to the whole problem was that tax collection was a Government job, and not the job of the doctors. A stamp method could be arranged, together with a system of exemption for old-age pensioners and others. Another member who supported the stamp method suggested that if patients turned up without a stamp they should give an IOU on a prescribed form. Others urged that methods of saving money on pharmaceutical services, quite apart from this impost, should be investigated. One of the visitors from the National Pharmaceutical Union, while agreeing that any extravagance there might be in prescribing was not intentional on the part of practitioners, suggested that some of it might be due to the fact that few practitioners were aware of the cost of drugs and particularly of proprietaries, and he thought that it would be useful if at some medical meetings demonstrations of pharmaceutical service costs could be arranged.

Almost No Grumbling from Patients

Several members of the Committee testified that from patients in general almost no grumbling was heard about the proposed charge. One member reminded the Committee that as citizens they could not ignore the economic position of the country; the gravamen of their complaint was that they had not been consulted from the start about the best method of effecting these economies.

Interview with Minister Sought

A long discussion ended in unanimous agreement to request an interview with the Minister himself, when the following points would be brought forward: (1) that the profession should have been consulted on the detailed application of the scheme and that consultation even at this late hour might be productive; (2) that the profession had alternative suggestions to offer and was anxious for a discussion on the whole question of economies in the pharmaceutical field; (3) that the position of the rural practitioner doing his own dispensing deserved special consideration, and (4) that hardship on certain special classes of patients—for example, those suffering from diabetes or pernicious anaemia—must be avoided. A resolution was passed that representatives of the Committee, in conjunction with representatives of the pharmacists, should seek an interview with the Minister on these lines with a view of bringing to his notice the difficulties arising from the unrealistic proposals of the Government concerning the charge on prescriptions, especially as affecting the dispensing doctor, who was expected,

to be an intermediary in collecting the charge, which was not part of the doctor's job and might well prejudice the doctor-patient relationship in a publicly organized service.

WORK OF MEDICAL PRACTICES COMMITTEE

Anxiety about Classification

Dr. W. E. DORNAN, chairman of the Medical Practices Committee of England and Wales, attended the meeting of the General Medical Services Committee in response to a request arising out of the anxiety expressed at the last Annual Conference concerning the criteria which his committee applied in classifying various areas throughout the country. Dr. Dornan said that his committee took all relevant factors into account before classifying any area. A doctor was free to practise wherever he wished except in those areas where the average list was so low that a waste of medical man-power would be entailed and the doctor himself would probably not be able to earn a satisfactory living. In closing areas with an average list of 1,600 or less, his committee was in no way implying that it was beyond the power of a practitioner to deal with a higher list.

He added that in fixing on a figure of between 1,600 and 2,000 average list as representing the limit above which they were not prepared to consider refusing any doctor the opportunity to go on the medical list, they had divided the low-list areas into two categories: those in which admission was unlikely to be granted and those in a doubtful category, these latter being multi-doctor areas where the admission of one more doctor would not appreciably reduce the 1,600-2,000 average. The committee had published schedules of areas so that doctors going into practice would know in which areas automatic admission would be granted, and the areas which were under-doctored and better-doctored. Whatever figure was taken must be interpreted with a certain flexibility. All along the line they had endeavoured to be as elastic as possible. They did not like splitting up large city areas, though there were some parts of cities where the average approached 4,000 while other parts would probably come into the schedule of better-doctored areas.

Appointment of Successors to a Vacancy

Dr. Dornan also, at the request of the Committee, made a statement on the procedure of the Medical Practices Committee concerning the appointment of successors to vacant practices. The matter had arisen from a resolution of an executive council urging that executive councils be given full power and responsibility for the final choice of the practitioners with whom they contracted to provide service in vacant practices, subject, of course, to the customary rights of appeal. The Association of Executive Councils desired to obtain the views of the British Medical Association in the matter before reaching a decision. The question of the difference in procedure obtaining in Scotland also came forward.

Some figures were first given by Dr. Dornan covering the last seven quarters. During that time the average number of new admissions to the lists of executive councils in England and Wales per quarter was 277 and the average number of withdrawals 208, a net increase each quarter of 69. These new admissions fell into a number of different categories: those admitted with permission to start new practices averaged 48 each quarter, and admissions for the purpose of practising on limited lists 57. Practitioners admitted to practices in partnership at the selection of the partner, already installed numbered 155 per quarter, of whom 83 were entirely new to the partnership practice and 72 had previously been in the practice as assistants. During the middle part of the seven quarters the admissions to partnership had averaged well over 200 per quarter and the total admissions 320.

In England and Wales, Dr. Dornan continued, the executive councils decided whether there was or was not a vacancy

in the practice and made a recommendation to the Medical Practices Committee accordingly. If they said there was a vacancy and it should be filled by advertisement the Medical Practices Committee said, "Go ahead, and tell us about it when you have done it." On the other hand, if the council notified a death or resignation but declared that there was no vacancy, his committee might have something to say in the matter. In England and Wales an average of between 30 and 40 practices were dispersed each quarter, and in the vast majority of these cases there was no disagreement between the two bodies. The practices were mostly those with small lists.

Questions were raised over the dispersal of any practice of substantial size, but his committee was usually convinced of the rightness of the procedure, and the last word was with the executive council. In Scotland, however, the Medical Practices Committee had an absolute right to insist on its point and, if so considered, to declare a practice vacant and advertise it.

Contrast with Scotland

In England and Wales, when applications were received by executive councils, a short list was prepared in most cases and candidates interviewed. In a few cases the Medical Practices Committee, acting on information, might make inquiries, as a result of which now and then someone other than the recommended candidate of the executive council might be appointed. In Scotland the Medical Practices Committee came into the picture only after the executive council had arrived at its decision and there was an appeal against it. The Scottish Committee's decision was limited to the choice between the selected candidate and the appellant; it could not look again at all the applicants for the appointment, whereas in England and Wales the Medical Practices Committee had that power. As against this, one virtue of the Scottish method was that it gave to the local body a good deal more determination in its local affairs.

It was said that the Scottish method saved time. On this point Dr. Dornan said that he had made certain estimations. In England and Wales he had taken 32 consecutive vacancies, of which 10 went to appeal. In the 22 no-appeal cases the average time between the date of advertisement and the completion of the appointment was just under eight weeks (in which period the M.P.C. procedure occupied just under one week), and in the 10 appeal cases the average period from advertisement to final settlement was 11 weeks. In Scotland in 18 consecutive cases, of which three went to appeal, the average time for the 15 no-appeal cases was seven weeks, and for the three appeal cases just over nine and a half weeks. Thus the no-appeal cases in England took on the average one week longer than in Scotland, but he thought that the extra week's delay was a small price to pay for the advantages which the English system offered.

He added that his committee was by no means satisfied with the present appeals machinery. They were agreed that there should be an appeal from themselves as the Medical Practices Committee—to the Ministry of Health if they pleased—but the machinery by which the Ministry reached its decision should be materially altered. Appeals were heard by the Ministry, the tribunal comprising a barrister and a medical assessor, but the latter was one of the Ministry's own officers, not necessarily one in touch with conditions of general practice. In reply to a question, he said that legal assistance was available on appeal and almost invariably practitioners were represented by counsel, though now and then a doctor would present his appeal himself.

The CHAIRMAN (Dr. Wand) suggested that Dr. Dornan's very full statement on this subject should be circulated to local medical committees, with a request that they give some attention to it, and that it should come forward at the next meeting of the G.M.S. Committee, when an opinion might be given on the respective merits of the English and Scottish systems.

This course was agreed to.

Value of Doctors' Premises

The Committee also considered at length a detailed report from a subcommittee which had been exploring the alternative methods of dealing with the question of the outgoing doctor's premises on a vacancy occurring in the practice. The subcommittee was not able to present an agreed report, and certain differing proposals were submitted. One point of agreement was that the doctor's premises should carry a functional value, by which was meant a value attaching to the house, with vacant possession, which had been adapted structurally for medical practice. A statement on the whole somewhat detailed matter will be included in the Annual Report of the Committee to come before the Conference of Local Medical Committees on June 12.

HOSPITAL PRESCRIBING**SENSE OF RESPONSIBILITY LACKING**

A letter from the Liverpool Regional Hospital Board to the secretaries of its hospital medical boards draws attention to "a certain lack of a sense of responsibility" in view of the rapid increase of expenditure on medical supplies in certain hospitals. Regional expenditure on vitamins during the year ending March 31, 1951, amounted to £11,211, which was 4.48% of the total expenditure on drugs. The board's committee "was convinced that so large a figure could be explained only by the existence of indiscriminate and unnecessary prescribing of these drugs."

Saving on Drugs

The average ratio of expenditure on proprietary drugs to that on non-proprietary drugs is said to be 1:2 in general hospitals, and general hospitals whose expenditure exceeds this ratio are to be asked for further information on the type of proprietary drugs prescribed. Hospital medical boards are asked to consider authorizing hospital pharmacists to substitute standard preparations for proprietaries if standard preparations are available with substantially the same or of reputed analogous therapeutic effect (unless the doctor specifies the proprietary is required). Saving in antibiotics is advocated and also of dressings, particularly gauze. Small tomograms are suggested as one way of cutting down use of x-ray films.

Other recommendations are that lists should be displayed showing current prices and local consumption of medical items, that pharmacists should draw attention to any marked increase in prices of drugs, and that it should be pointed out that pharmacists have the right to refuse drug orders not correctly prescribed.

Emergencies Refused

A report of another of the board's committees deplores the fact that "an increasing number of true emergencies are being refused admission by many general hospitals in the region when beds are known to be available." Measures for remedying this are described.

IDENTITY CARDS ABOLISHED

Though National Registration identity cards have been abolished, people who use the National Health Service still need to be numbered. People who had identity cards will continue to have these numbers in the Health Service records. Babies and others who did not come under the National Registration will be given numbers for the N.H.S. The Ministry of Health asks doctors in their own interests to obtain the N.H.S. number from any patient wanting to go on their lists and to quote the number when required—for example, on maternity and temporary-residents forms.

Scottish News**G.M.S. SUBCOMMITTEE (SCOTLAND)**

The General Medical Services Subcommittee (Scotland) met at B.M.A. House, Edinburgh, on January 31, with Dr. J. T. BALDWIN (Milton Bridge) in the chair. The Subcommittee received with regret the resignation of Dr. F. McEwen Sinclair, who had been the representative of the Fife Local Medical Committee for a number of years. It was agreed that a letter should be sent to Dr. Sinclair expressing appreciation of his services as a member of the Subcommittee, and also of the services given as a member of the Insurance Acts Subcommittee (Scotland).

It was intimated that Scotland had now two representatives on the Assistants and Young Practitioners Subcommittee of the G.M.S. Committee. The representatives were Dr. G. C. Malloch (Armadale), representing the assistants in Scotland, and Dr. J. Shapero (Glasgow), representing the unestablished practitioners.

Liaison in Health Service

The Subcommittee considered further the proposal by the Department of Health to appoint, as an experiment in a few selected areas only, regional medical officers to the general-practitioner service for the purpose of liaison between the three branches of the Health Service and to assist in day-to-day routine matters. After a lengthy discussion, during which particular attention was paid to the proposal in the light of the Scottish Health Services Council's report on the general-practitioner and hospital service, it was decided that the proposal should again be discussed with the Department to clear up one or two points and to seek an undertaking that if the Subcommittee, on examining the working of the scheme, after a specified period, should find it to be serving no useful purpose it would be abandoned. The final decision on the matter was deferred until the next meeting of the Subcommittee.

It was agreed that after the G.M.S. Committee had concluded its examination of the medical service committee and tribunal procedure the Chairman's Subcommittee of the G.M.S. Subcommittee (Scotland) should examine the position from a Scottish point of view and in the light of the G.M.S. Committee's findings.

Inflation of Lists

There was considerable discussion about the procedure for the elimination of inflation of lists. The Subcommittee expressed itself as being in agreement with the amended procedure which the Department had decided to put into operation as a result of representations by the Subcommittee. The following is a summary of the essential points in this agreement:

(1) It is appreciated that many doctors, especially during the first three months of the year, which have normally a heavy sickness incidence, will not find it practicable in the time allotted to carry out the work entailed in trying to trace those patients notified to them on Form E.C.S. 75B.51. The Secretary of State accordingly has authorized the following modifications in the arrangements.

(2) Executive councils should regard the three-month period as the *minimum* of time to be given to a doctor under the regulations to report on any patient notified to him on Form E.C.S. 75B.51.

(3) Where a doctor on examination of the list of persons sent to him is satisfied as regards any of them that either they cannot be traced or they are no longer resident in his area and he is no longer responsible for the provision of treatment in respect of such persons, he should be asked to inform the clerk of the council accordingly and such persons will be removed from his list with effect from April 1, 1952.

(4) The doctor should be asked to notify the clerk of the council as soon as possible of any persons he has traced or whose

whereabouts he thinks he can determine without much trouble. He should supply the council with such particulars regarding these persons as he can obtain—e.g., present address, National Registration number, name (if name has been changed). The absence of an identity number will not of itself mean that a patient will be removed from a doctor's list.

(5) In regard to the remainder of the persons notified to the doctors and not disposed of under paragraphs 3 and 4 above, if a doctor has good reason to believe that they are still resident in the practice area, and might be traced, he should be asked to inform the clerk to the council accordingly. The council should give the doctor whatever assistance it can in a fresh endeavour to find these persons. Such assistance would include the issue of a further letter to the person at his last known address.

Local authority housing factors may be in a position to assist the council by supplying the present address in the case of any persons who have been rehoused.

(6) Persons in the category covered by paragraphs 4 and 5 above and who have not been traced by the end of June, 1952, will be removed from the doctor's list with effect from July 1, 1952. Should a doctor be able to add to the names notified to the council under paragraph 3 above before March 31, 1952, the council would arrange to remove them from his list with effect from April 1, 1952.

The Subcommittee expressed itself as being fully aware of the difficulties being experienced by practitioners as a result of these investigations. It was agreed that in cases of difficulty secretaries of local medical committees should consult with the clerks of executive councils in an endeavour to clear up any problems, and if such a meeting was unsuccessful that the secretary of the local medical committee should contact the Assistant Scottish Secretary, who would arrange for a meeting between the clerk of the executive council, the secretary of the local medical committee, and a representative of the Department in an endeavour to make things easier for everyone concerned. The Department had indicated its willingness to co-operate in any way possible.

Practice Vacancies

The Subcommittee then considered the question of practice vacancies occurring in areas where the practice was in more than one executive council area. It was agreed to refer to the liaison committee between the Scottish Association of Executive Councils and the General Medical Services Subcommittee (Scotland) the possibility of having proportional representation of executive councils on the committee making the appointment in such a vacancy.

Shilling on Prescriptions

The Subcommittee considered the proposed charge of 1s. for each prescription, as introduced by the Chancellor of the Exchequer as an emergency measure. The Subcommittee felt that practitioners should not be required to collect this money.

CENTRAL CONSULTANTS AND SPECIALISTS COMMITTEE (SCOTLAND)

The Consultants and Specialists Committee (Scotland), at a meeting at B.M.A. House, Edinburgh, on January 28, received with great regret from Mr. T. Murray Newton his resignation on medical grounds from the chairmanship of the Committee. Dr. J. G. M. HAMILTON, Edinburgh, vice-chairman, was appointed to the chair, and Dr. I. D. Easton, Perth, was appointed vice-chairman.

Need for Economy

In connexion with the need for economy in the affairs of the Association, it was pointed out that in the past the Association had paid the whole secretarial and clerical expenses incurred by Regional Consultants and Specialists

Committees. It was decided that in future these costs should be borne by the Central Consultants and Specialists Fund; other economy measures in connexion with the meetings and the conduct of these were also approved.

Anaesthetic Services

Following the decision to set up a Central Anaesthetic Services Subcommittee, it was agreed that the constitution should be: chairman and vice-chairman of the Central Consultants and Specialists Committee (Scotland), six consultants or S.H.M.O. anaesthetists appointed regionally thus—Western Region two, Northern one, North-eastern one, Eastern one, and South-eastern one—the Scottish representative on the B.M.A. Anaesthetic Group Committee, and one representative from the General Medical Services Subcommittee (Scotland). The reference, it was decided, should be: "To consider and report to the parent committee on all matters relating to the anaesthetic service under the National Health Service (Scotland) Act."

Hospital Staffing

On the question of the Department of Health's proposals on the structure of hospital medical staffing, it was reported that at a meeting of the Scottish Joint Committee and officials of the Department it had become apparent that there were a number of misconceptions about the nature of the department's proposals. A small subcommittee was appointed to examine these aspects, and it was hoped that at an early date there would be submitted a report on which the Central Consultants and Specialists Committee (Scotland) could decide policy.

Regional Appeals

A report was also received that it had been ruled that regional appeals involving appointing authority's discretionary powers were not competent under the present regional appeals arrangement. As some of the appeals at present outstanding in Scotland relate to the exercise of a board's discretionary powers, it was decided that the Scottish Joint Committee be asked to discuss with the department the application of the regional appeals machinery to cases in which consultants felt that they had been unjustly, as opposed to incorrectly, treated by their appointing authority.

Alteration of Contracts

Attention was drawn to a letter now being issued by regional hospital boards to consultants, proposing the insertion of an additional clause in their contracts defining more precisely the procedure under which boards may alter contracts in respect of variations in duties and number of sessions. It was pointed out that the Scottish Joint Committee had accepted the proposed clause as reasonable, but, when some concern was expressed, it was agreed that an explanatory communication should be sent to Regional Committee secretaries and that the matter be considered at the next meeting.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Southwark, Stoke Newington.

Non-County Borough Councils.—Crewe.

Urban District Councils.—Droylsden, Houghton-le-Spring, Huyton-with-Roby.

Correction.—Sir Richard Croft was erroneously called Sir John Croft (*Supplement*, February 16, p. 63) in our reference to the physician who attended Princess Charlotte, daughter of George IV.

Correspondence

Health Service Charges

SIR,—Although retired after 60 years in general practice, and therefore having no axe to grind, I view with real concern the provisions set out in the present National Health Service Bill for making a charge of 1s. on each doctor's prescription. This to my mind means an inevitable if only a restricted bar to the doctor prescribing what he or she deems fittest and best for the patient, though this may be only what is termed a "placebo." I feel sure if the Bill comes into force it will tend to debar patients from consulting their doctors at all and drive them to buy more and more proprietary medicines.

Surely if these millions of revenue have to be raised or saved it could best be through the income and "pay as you earn" taxes. What benefits the whole community should be paid for by the whole community. Although I am a loyal supporter of the present Government, I consider this Bill bad in every way—politically, financially unfair, and most difficult to administer.—I am, etc.,

London, N.13.

ALEX P. AGNEW.

SIR,—I cannot understand why this tax or charge is not placed on the bottle or container rather than on the prescription. This would solve most of the difficulties inherent in the suggested scheme. It would cause little hardship and would save an enormous amount of waste. I believe it would be readily accepted by the chemists, and I can see no reason why the doctors should object to it. A similar system worked before July, 1948.

The scheme as reported (*Supplement*, February 9; p. 47) would be very difficult to carry out and would bear heavily on the really sick person and the aged, and would not be so effective in reducing the very large wastage of fuel, transport, and glass which the present system allows.—I am, etc.,

Coventry.

T. B. KENDERDINE.

SIR,—The proposal to tax prescriptions in order to reduce the cost of the national medicine bill surely infers criticism of the medical profession who issue the prescriptions, the grounds for the proposal being that consumption is excessive. If deterrents must be introduced, would it not be more just to apply them to the doctors who, by their prescriptions, authorize the issue of medicines? This could be effected by requiring each practitioner to purchase his book of E.C.10 forms as he does his cheque book at, say, 3d. per form. He could be reimbursed by having the capitation fee increased by 1s. on the grounds that each patient receives four prescriptions annually, judging by current figures. Further "deterrents" would be applied, on a sliding scale, to prescriptions costing more than, say, 5s.

There cannot be any genuine objections to such a proposal, for it is under a system very similar to this that the rural dispensing practitioner works now. It would of course deal a mortal blow to the practices with large lists, dependent as they are for their management on the slick use of prescription forms without much regard to the cost.—I am, etc.,

Uffculme, Devon.

FRANK MURRAY.

SIR,—I must refer to the correspondence appearing in your columns anent the proposed charges for prescriptions under the National Health Service, and would agree with all who have raised their voices against it. However, economies are necessary, and one's thoughts are directed to another method of reducing the cost of prescriptions, bearing in mind that a considerable proportion of old-age pensioners would have been entitled to free medical treatment for life under the previous insurance scheme, and taking into account any way of lightening the burden of G.P.s in general.

A perusal of the analyses given in a report of the survey of National Health Service prescriptions (*Journal*, February 9, p. 292) shows that 21% of the prescriptions dispensed relate to proprietary preparations. If, therefore, a ban were placed on the prescribing of such preparations under the National Health Service, a saving of well over 5% on prescription costs would be achieved. It would also serve to reduce many of the frivolous demands by patients who would not otherwise be deterred by the payment of a mere fraction of the cost of these preparations.

Who knows: if such a scheme were adopted, the new Minister of Health might agree to raise the central pool by 50% of any saving in excess of 5% on the pharmaceutical services?—I am, etc.,

Southport, Lancs.

E. PEARSON.

SIR,—By what authority has an "autonomous body" of the Association issued a statement to the public press saying that the British Medical Association is "disturbed" over the Government's proposals to introduce charges for prescriptions? Was the Council of the British Medical Association consulted? Considering that in all probability the majority of the profession agree that some charges are necessary, the G.M.S. Committee seems to be out of tune with the rank and file.

It would appear that the G.M.S. Committee is rapidly turning itself into an extension of the Ministry of Health. Its members seem to have forgotten that they were elected to represent their colleagues, not to administer the National Health Service, nor to express, in a roundabout manner, the views of Civil Servants in the Ministry.

It is quite noticeable that the members reported as having taken part in the discussion on this problem, with one exception, represent a certain point of view, which is quite definitely not the point of view of the profession nor indeed of the British Medical Association as defined by the Representative Body. The secretary of the Medical Practitioners Union made certain statements which are quite irrelevant. This is not a question of paying twice for the same thing: this is a question of finding enough money to keep a bad scheme going. I have never noticed a similar protest from the M.P.U. when the price of other commodities increased, such as coal or transport. Many of us feel that psychologically, far from being a barrier, it would be much better for the patients' appreciation of the Service if some percentage charge were made throughout the Service. Personally, I am not convinced of the best method of introducing this, but I am equally unconvinced that "free at the time" service or the capitation method of payment is good.

It is a tragedy that we have no leaders like those of the B.M.A. in New Zealand, who were willing to accept and overcome a threat to remove their licences to practise before they got a National Health Service to their liking after 10 years' fight. Our leaders, for all their protestations in 1948, have accepted this patchwork scheme lock, stock, and barrel.—I am, etc.,

London, W.C.1.

J. L. McCALLUM.

The School Medical Service

SIR,—The problem of bringing about a closer liaison between the school health service and the family doctor" referred to in the report of the Chief Medical Officer of the Ministry of Health, and noted in the *Journal* of January 26, (p. 210), is indeed complex. So much so that one is tempted to ask, Why try to solve it at all?

Why not let the school medical service, with its staff of doctors, health visitors, and nursing assistants, its clinics, and school medical rooms, take over the care of children in sickness as in health? Why not build up a semi-specialist service for children based on the home and the school, thus cementing these two important elements in a child's life more firmly together and forming a powerful bridge of understanding between the two?

At first sight such an idea may seem rather shocking, almost indecent, but consider the following points. The old-

fashioned family doctor has become a relic of yesterday just as the present school medical service has become an anomaly of to-day. Past improvements in child health have been largely due to better maternity and child welfare clinics, school milk, school dinners, and improved physical training in the schools—all background features of the school medical service.

A comprehensive child health service could provide treatment for sick children in their private homes, help with their sexual and psychological adjustments, supervise their care in health, and help teach hygienic habits. The single service could be ideally adapted to the needs of parents and teachers, would draw the school and home closer together, would provide interesting work for doctors and nurses, and would solve the problem of a better liaison between the family doctor and the school medical service. On leaving school children could be handed on to the family doctor with a summary of their childhood medical histories.

Surely such a single service would be preferable to the present double one, which limits the school medical service to the supervision of healthy (and for the most part normal) children and does little to draw the home and school more closely together.—I am, etc.,

Newton Abbot, Devon.

W. G. HUTTON.

Fees for Lectures to Nurses

SIR.—The scale of fees for lectures to student nurses negotiated in Whitley Council (*Supplement*, February 2, p. 43) cannot be allowed to pass unchallenged, since it is extremely unfair to members of hospital medical staffs.

Ability to lecture to student nurses cannot be related to "grading"; it depends on teaching aptitude and experience. Moreover, the lecturer, whatever his grade, must prepare his material with great care so that he can present it in a clear and simplified form to his students. Another point to be remembered is that these lectures often have to be given at inconvenient hours in order to fit in with hospital routine.

The scale of fees agreed compares unfavourably with less important teaching undertaken by medical men. The B.M.A. has negotiated a minimum fee of £1 11s. 6d. for doctors lecturing to laymen on first aid, while some polytechnics and training colleges pay £2 2s. per lecture for similar work.

The minimum fees for these lectures should be £2 2s. whatever the grading of the member of the medical staff, and for this principle the B.M.A. should fight immediately.—I am, etc.,

Wimbledon, Surrey.

A. DAVID BELILIOS.

Visitors from Abroad

SIR.—It appears that people arriving in this country from abroad are no longer provided with Form E.C.1 (Med.) or any other instructions to register with a doctor. I have had two within a week, one expecting to stay 12 months, the other nine months, so both are too long to be temporary residents.

As doctors we carry the risk and responsibility, but it does not appear that we receive any payment for the risk, but only for actual attendance. It may be said that we do receive an intangible fragment of payment from an invisible pool. If so, it is an unsatisfying form of sustenance unlikely to be approved by any experienced personnel relations officer.—I am, etc.,

Crowthorne, Berks.

H. D. FORBES FRASER.

Prescribing and the Public

SIR.—In spite of the fact that prescribing costs in England are lower than in Northern Ireland (*Supplement*, February 2, p. 43), I consider that a similar notice to the one supplied to Northern Ireland doctors would be of great help to practitioners in this country. Such a notice, prominently displayed in one's surgery, would go a long way to checking the minor abuses of the N.H.S. which are still a source of irritation to the majority of practitioners.

I know that at the moment one is fully entitled to resist unreasonable demands by patients, but in my experience this nearly always leads to bad feeling or a lengthy discussion, neither of which is to be desired. An official statement of policy, such as described in the *Supplement*, is to my mind second in importance to the question of general-practitioner remuneration. I sincerely hope that this matter will not take three and a half years to reach a stage of adjudication.—I am, etc.,

Hayes, Middlesex.

S. EDELMAN.

Whole-time Salaried Specialists

SIR.—As President of the Association of Whole-time Salaried Specialists, I have noted with pleasure from the Proceedings of the Council (*Supplement*, February 2, p. 38) that the B.M.A. has decided to examine the position of practitioners in whole-time salaried appointments in relation to income tax with a view to the submission of evidence to the Royal Commission on Income Tax. I should like to draw attention to the fact that the Association of Whole-time Salaried Specialists has already submitted a memorandum to the Royal Commission on this subject drawn up in consultation with an income-tax expert.—I am, etc.,

London, W.C.2.

RUFUS C. THOMAS,

President, Association of Whole-time Salaried Specialists.

Paying for the Health Service

SIR.—Mr. Hilary Marquand (*Journal*, February 2, p. 272) exhibits a politician's view of the Health Service when he says that the public will only use it economically when they realize who pays for it. Modern preventive health medicine emphasizes early diagnosis and treatment. Only the trained expert can find out. The public's economical use of the Service can only be fairly rationed out by the medical and allied professions. Who pays for it appears irrelevant.—I am, etc.,

Honicknowle, Devon.

G. H. MILES.

SIR.—I was very interested to learn from his letter (February 2, p. 272) that Mr. Hilary Marquand believes one of the causes of extravagant use of the Health Service is the misunderstanding that it is paid for by the Insurance Fund. I find the misunderstanding is very common, and I believe it has arisen partly from the association of health and insurance in the old National Health Insurance and partly from the publicity put out by the Government in 1948. At that time I formed the impression that the Government was intentionally encouraging the persistence of the belief that the weekly contributions paid for the Health Service, in order to induce the more well-to-do section of the population to register with doctors and get their money's worth.

I am in no doubt that this misunderstanding did much to bring the wealthier to the surgeries and hospitals, and helped to achieve the very general acceptance the Health Service received. I never noticed that the late Government took any useful steps to correct the misunderstanding; perhaps the present Government will.—I am, etc.,

London, S.W.1.

GEOFFREY HALE.

Strange Encounter

SIR.—I received on the afternoon of Christmas Eve the following telegram: "Please meet me Ribble bus station Preston 8 o'clock. P." I spent a rather agitated hour wondering who could have sent this cryptic message, which, on inquiry at the Post Office, I discovered had been handed in at Blackpool by a person signing herself "Mrs. P." With no great stretch of the imagination one can understand just how puzzling this message was, as I know no Mrs. P. resident or non-resident in Blackpool.

However, my evening surgery on Christmas Eve did not finish until 8.15 p.m., and I could not make the 12-mile journey from my home in Blackburn to Preston. At 8.30 p.m. an aggrieved female voice sounded on my telephone inquiring had I not got the telegram and complaining of being kept waiting in the rain. The owner of this

voice subsequently divulged that she was a relation of a patient of mine and was anxious about her and wished to talk to me.

I will refrain from comment on this episode, which caused me some perplexity and anxiety, except to add that the time is ripe for even the wormiest of G.P.s to turn. B.M.A. negotiators please note.—I am, etc.,

Blackburn, Lancs.

A. C. SMERDON.

POINTS FROM LETTERS

Telling the Public

Dr. A. C. SOMMERVILLE (East Grinstead, Sussex) writes: Surely, Sir, we G.P.s are educated men and women and can be trusted to manage our own affairs—as we did before 1948—without the help of appealing to the B.B.C. or appealing for regulations to be drawn up, which incidentally could seldom be enforced, to control the so-called public. . . .

Dr. L. F. EVANS (Bolton, Lancs) writes: I would like to associate myself with the suggestion put forward by Dr. D. R. MacDonald (*Supplement*, February 2, p. 45). In addition I would like to suggest that local P.R.O.s should bring Dr. S. Wand's address to the notice of their local press, when I am sure it would be welcomed as good copy. . . .

Loath to Take Partner

Dr. H. FIRMAN (North Wingfield, Derbyshire) writes: Dr. W. Watson Newton's letter (*Supplement*, February 2, p. 45) displays to a nicety why, because of the attitude of mind of a certain section, G.P.s are being handicapped in their struggle for better remuneration and working conditions. . . . Has he ever stopped to give a thought to the large numbers of our brethren who are trying to make ends meet with a list of 1,000 to 2,000? Until there is a substantial rise in the capitation fee, there exists no ray of hope that these unfortunate colleagues will be able to improve their pitiful financial lot. As matters stand at present, it is necessary to have a list of at least 3,000 before one can reach a reasonable standard of living. It follows, therefore, that practitioners are loath to reduce their lists, or to take in a partner, until such time as the capitation rate is substantially raised. . . .

Early Call

Dr. S. J. HOWARD (Ivybridge, Devon) writes: Is this a record? I was telephoned to-day at 5.30 a.m. and asked to pay a routine visit.

Association Notices

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships, as follows:

An Ernest Hart Memorial Scholarship, of the value of £250.

A Walter Dixon Scholarship, of the value of £250.

Four Research Scholarships, each of the value of £200.

These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease.

Each scholarship is tenable for one year, commencing on October 1, 1952. A scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research, but may be a member of H.M. Forces or may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointment will not, in the opinion of the Science Committee, interfere with his or her work as a scholar.

Applications for scholarships must be made not later than March 31, 1952, on the prescribed form, a copy of which will be supplied on application to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

Branch and Division Meetings to be Held

EAST HERTS DIVISION.—At County Hospital, Hertford, Thursday March 6, 8.30 p.m., address by Professor W. C. W. Nixon: "Analgesia in Labour." To be illustrated with lantern slides.

HAMPSTEAD DIVISION.—At Hampstead General Hospital, Wednesday, March 5, 8.30 p.m., meeting. Talk by Mr. A. J. Gardham. All medical practitioners in the area of the Division are invited.

NUNEATON AND TAMWORTH DIVISION.—At Red Lion Hotel, Atherstone, Tuesday, March 4, 8 p.m., informal supper; 8.45 p.m., discussion: "Peptic Ulceration." To be opened by Dr. J. C. Neill, Dr. E. A. Hoare, and Mr. L. E. Jones.

REIGATE DIVISION.—At Redhill County Hospital, Tuesday, March 4, 8.30 p.m., Dr. Clifford Hoyle: "Doubtful Chests."

ST. PANCRAS DIVISION.—At Old Library, B.M.A. House, Tavistock Square, London, W.C., Tuesday, March 4, 8.30 p.m., lecture by Professor L. P. Garrod: "The Intelligent Use of Antibiotics."

SOUTH BEDFORDSHIRE DIVISION.—At Luton and Dunstable Hospital, Friday, March 7, 9 p.m., Mr. N. R. Barrett: "Cardiac Surgery" (illustrated).

SOUTH ESSEX DIVISION.—At King's Head Hotel, Market Place, Romford, Thursday, March 6, 7.30 p.m. to 1 a.m., annual supper dance and cabaret.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.—At Morriston Hospital, Swansea, Thursday, March 6, 3 p.m., joint clinical meeting of Branch and Swansea Division. Cases will be shown.

WANDSWORTH DIVISION.—At St. James' Hospital, Ouseley Road, Balham, London, S.W., Tuesday, March 4, 8.45 p.m., lecture by Dr. T. H. Howell: "The Medical Care of the Aged." To be illustrated by cine films.

WEST BROMWICH AND SMETHWICK DIVISION.—At the Red Cow, High Street, Smethwick, Friday, March 7, 8 p.m., dinner dance; dinner 9 p.m.

Meetings of Branches and Divisions

HOLLAND DIVISION

A meeting of the Holland Division was held on February 1 at Boston (attendance 33). The chair was occupied by Dr. Gerald Walker and an address was given by Dr. William Tegner on "The Management of the Rheumatic Patient." The lecturer covered an extensive and interesting range of treatments which were in favour in the past and at the present time. His helpful observations on the results obtained in his considerable experience were received with very evident interest by his audience. Some forecasts concerning the probable availability of some of the newer remedies were mildly encouraging.

A hearty vote of thanks was accorded to Dr. Tegner on the proposal of Dr. R. E. Crockatt, who expressed thanks to him for his kindness in travelling to such relatively remote parts for the purpose of imparting some very interesting information and for the delightful manner in which it was presented.

Are Vaginal Tampons Prejudicial to Health?

An Investigation* concerned with the bacteriology of vaginal flora following the use of internal tampons was undertaken at the request and with the co-operation of the visiting gynaecologists to a London Women's hospital.

It is gratifying to find that this investigation confirms earlier work carried out in America and gives further support to the claim that Tampax can be confidently recommended as a convenient, comfortable and safe form of sanitary protection.

** Tampax tampons were used in this investigation.*

EXTRACTS FROM THE REPORT:—

- ★ "Smears and cultures taken before and after each period showed no appreciable change in the bacterial flora of the vagina."
- ★ "None of the volunteers acquired monilia or trichomonal organisms during the period of study or developed erosions or vaginitis as a result of using the internal tampon."
- ★ "There was no aggravation of the condition or delay in healing following the use of tampons in the patients who had cervical erosions."
- ★ "In each case the underlying cause responded to treatment, and did not recur, which proves that the internal tampon does not act as an irritating foreign body."
- ★ "The rate of healing compared favourably with four control cases in which the perineal pad was used."
- ★ "The glycogen content was uninfluenced by the use of tampons."
- ★ "There was no appreciable alteration in the pH in the pre- and post-menstrual phases."
- ★ "Volunteers who had not previously used tampons stated that they did not cause the irritation usually found with the perineal pad."
- ★ "There was no evidence that vaginal tampons are prejudicial to health."

British Medical Journal, 1, 24 (1952)

Literature and professional samples of Tampax will be sent on request to:

EDICAL DEPARTMENT, TAMPAX LIMITED, 110 JERMYN STREET, LONDON, S.W.1

Spencer Antepartum-Postpartum Support

A Spencer supports the breasts in position to improve circulation; protects inner tissues; helps prevent skin from breaking. Guards against caking and abscessing after childbirth.

Do not overlook the Psychological effect of a SPENCER Support

During antepartum and postpartum periods—and especially in early ambulation—a Spencer exerts an important psychological effect. A Spencer's gentle but effective support increases the patient's confidence in her ability to "stay on her feet" and "move about."

Therapeutically, a Spencer Support helps to regain postural stability, helps replace organs in normal position, often relieves low-back pain. A Spencer offers protection to tissues affected by operative procedures without restricting natural muscle activity.

A qualified scientifically trained Fitter furnishes us with a description of the patient's body and posture, and detailed measurements. Then the support is individually designed, cut, and made at our Manufactory at Banbury. Within a short time the patient's support is delivered and adjusted by the Fitter.

For further information and Brochure on Spencer Supports write to:

EPHAZONE tablets

*Rational, symptomatic
treatment in
Asthma & Bronchitis*

Each tablet contains Ephedrine, the important anti-spasmodic for bronchial spasm, Theobromine, for its relaxing effect on the bronchial muscle and for stimulation of the coronary circulation, Phenazone, for its soothing effect on the higher centres, and Calcium gluconate, a readily absorbable calcium salt, for diminishing capillary permeability and checking the secretion of mucus.

These active ingredients with complementary effects in bronchial asthma are presented in the following proportions in the 'EPHAZONE' Tablet:

Ephedrine hydrochloride	- - -	$\frac{1}{2}$ grain
Theobromine	- - -	$\frac{1}{2}$ grain
Phenazone	- - -	1 grain
Calcium gluconate	- - -	$\frac{1}{2}$ grain

This preparation is sanctioned for prescription under N.H.S. Please write for samples and descriptive leaflet.

The Postural Reflexes Remain Intact

VERILOID

Trade Mark

In Hypertension

A highly valuable feature of the hypotensive action of Veriloid is the continued functioning of the postural reflexes so important to normal living. Even when the blood pressure is lowered to normal or near-normal limits, exertion and sudden changes in posture lead to the physiological adjustments in cardiovascular dynamics which are needed to prevent acute hypotensive episodes or collapse.

Veriloid, a distinct, biologically assayed hypotensive fraction of *Veratrum viride*, finds great usefulness even in the more severe and resistant forms of hypertension. For most patients the average daily requirement of 9 to 15 mg. given in divided dosage three times daily is adequate, although individualization of dosage is essential for maximum therapeutic efficacy and prevention of reactions.

Veriloid is available on prescription through all pharmacies in 1 mg. tablets. It may be prescribed on Form E.C.10 without restriction. Literature available on request.

RIKER LABORATORIES, LTD. • 29 KIRKEWHITE STREET, NOTTINGHAM

Kaylene-ol in Upper Respiratory Infections

The common cold, sinusitis, tonsillitis, and other inflammatory conditions of the nose and throat lead inevitably to the swallowing of infected exudates.

The digestive tract, deranged by toxins, bacteria and fever, is ill-prepared to receive them.

The routine use of Kaylene-ol on these occasions does much to normalise the gastric and intestinal functions, and to nullify the harmful effects of noxious discharges.

DOSAGE: 1 to 4 drachms of KAYLENE-OL night and morning, or preferably 20 minutes before each meal.

Samples and literature on request

Pre-Natal Diet and the course of Pregnancy

The normal functioning of the reproductive organs during pregnancy depends, among other things, upon the plentiful intake of vitamins and minerals.

Medical opinion is gaining ground that there is an increased need for Vitamin B in late pregnancy and the early puerperium. Its administration during the period before childbirth has resulted in less vomiting and nausea and in marked improvement in the nutritional value of the breast milk. In order to assure the building of the foetal bones *in utero* and afterwards during breast-feeding, the importance of Vitamin D and of calcium and phosphorus is also established.

In Supavite Capsules the practitioner has at hand a combination of these and other essential vitamins and minerals in a scientifically balanced form of particular value in maternity cases.

Angiers
SUPAVITE
CAPSULES

FORMULA

Each **AMBER** Capsule contains:
Vitamin A .. 6,000 I.U.
Vitamin D .. 1,000 I.U.
Vitamin E .. 1 mg. plus
one minim wheat germ oil.

Each **BLACK** Capsule contains:

A CAREER AT SEA FOR YOUR SON

The Merchant Navy offers good prospects

The large Shipping Companies recruit future Executive Officers for their ocean-going ships from H.M.S. Worcester, a Nautical College founded in 1862 by London shipowners. Nearly 7,000 Cadets have passed through the College and received specialized training in addition to a sound general education.

The College is officially recognized by the Ministry of Education and by the Ministry of Transport, the latter accepting the training provided on board the Worcester as being the equivalent of one year's sea service.

Cadets are admitted after reaching the age of 13½ and before reaching the age of 16. They leave the College when they are 17 and the period of training depends on the age at entry, with a minimum period of two years. Candidates are required to take the Common Entrance Examination or the Worcester Entrance Examination, according to age. They must be medically fit with perfect eyesight.

Fees are £180 per annum including uniform. Various scholarships in reduction of fees are available, varying in value from £180 p.a. to £50 p.a. The Worcester offers an excellent opportunity for boys of good education and character wishing to become Executive Officers in the Merchant Navy—a career providing world travel, good remuneration and an interesting life.

Illustrated Prospectus containing full information will be forwarded on application to the Secretary,

**INCORPORATED THAMES NAUTICAL TRAINING COLLEGE,
H.M.S. WORCESTER.**

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.

Deferment of call-up for "R" practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R" practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R" practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R" practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Registrar Grades, Whole-time

(a) **REGISTRAR**: Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR**: Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years: £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER**: £350 per annum for the first post held, £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER**: Posts obtained normally not less than one year (in Scotland, two years) after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER**: Officers who have held house appointments but who are not Registrars and who have less responsibility than other hospital officers of non-consultant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement.

APPOINTMENTS**ANAESTHETICS****BRISTOL CLINICAL AREA**
South-Western Regional Hospital Board

Applications are invited from registered medical practitioners for the appointment of

WHOLE-TIME CONSULTANT ANAESTHETIST

to the Bristol Clinical Area, which comprises Bristol and the adjoining districts of Gloucestershire and Somerset. The successful applicant will be required to work at Southmead Hospital, Bristol, which has 126 surgical beds and 133 obstetric beds, and to visit other hospitals in the clinical area as may be determined by the Regional Board from time to time. Preference will be given to candidates who are interested in anaesthetics and analgesics in obstetric practice. Candidates are invited to visit the hospitals concerned, and should communicate with the Secretary of the Southmead General Hospital Group Management Committee.

Twelve copies of applications, stating date of birth, qualifications and experience, together with twelve copies of two testimonials, and the names and addresses of two referees, should be sent to the Secretary of the Regional Hospital Board, 5, Cotham Lawn Road, Bristol, 6, not later than March 20, 1952.—(8718)

LIVERPOOL REGIONAL HOSPITAL BOARD
Applications are invited for the post of

PART-TIME CONSULTANT ANAESTHETIST

to hospitals in the undermentioned areas: (a) Liverpool Groups for seven notional half-days weekly. Experience in anaesthesia for chest surgery would be an advantage. (b) Southport and Ormskirk for maximum part-time sessions. (c) Birkenhead and North Wirral for seven notional half-days weekly. (d) Central Wirral and Chester for seven notional half-days weekly. Applicants must possess the D.A. and should have had considerable experience in the administration of anaesthetics. Forms of application from, and to be returned to, Dr. T. Lloyd Hughes, Senior Administrative Medical Officer, Liverpool Regional Hospital Board, 19, James Street, Liverpool, 2, to be received not later than March 15, 1952.—Vincent Collinge, Secretary to the Board.—(8826)

LEEDS REGIONAL HOSPITAL BOARD
Applications are invited for the appointment of

WHOLE-TIME ASSISTANT ANAESTHETIST

(S.H.M.O. scale)
for duties at hospitals in the Hull (A) and East Riding Hospital Management Committee Groups. The successful candidate will be required to reside in or near Hull or within such distance of that town as the Board may approve. Applications, stating age, qualifications and details of present and previous appointments (with dates), together with the names of three referees, should be forwarded to the Secretary, Park Parade, Harrogate, not later than March 29, 1952.—(8687)

MANCHESTER REGIONAL HOSPITAL BOARD
Applications are invited for the, whole-time non-resident post of

ASSISTANT ANAESTHETIST

to work under the general guidance of the Group Consultant at the Oldham Group of Hospitals (Oldham Royal Infirmary, Boundary Park General Hospital, etc.). Salary £1,300 by £50 to £1,750. The successful candidate will be required to live near Oldham. Forms of application may be obtained from the Senior Administrative Medical Officer, Manchester Regional Hospital Board, Cheetham Road, Manchester, 8, and should be returned, together with the names and addresses of three referees, to be received not later than March 15, 1952.—(8761)

SCOTLAND, WESTERN REGIONAL HOSPITAL BOARD

Applications are invited from suitably qualified medical practitioners for the following appointments:

WHOLE-TIME ASSISTANT ANAESTHETIST

based upon the Western Infirmary, Glasgow. Salary on the scale £1,300 by £50 to £1,750.

WHOLE-TIME ASSISTANT ANAESTHETIST

for duties in the Lanark County Area, based at Stonehouse Hospital. Salary on the scale £1,300 by £50 to £1,750.

Applications (sixteen copies), stating age, qualifications and experience and present appointment, and giving the names of three referees, should be submitted, not later than thirty days after the publication of this advertisement, to the Secretary, Western Regional Hospital Board, 64, West Regent Street, Glasgow, C.2. The above appointments will be subject to the National Health Service (Scotland) (Superannuation) Regulations, (8812)

Anaesthetics—contd.**BRISTOL, UNITED, HOSPITALS**
(Joint Appointment with the South-Western Regional Hospital Board)

Applications are invited by the above Boards from registered medical practitioners for the joint appointment of

ANAESTHETIC REGISTRAR

The appointment will be subject to the terms and conditions of service of hospital medical and dental staff negotiated between the Minister and the profession. The successful applicant will be appointed to work in the first instance for one year in the United Bristol Hospitals. Applications, giving full Christian names, particulars of age, qualifications, and experience, and the names of two referees, should be sent not later than March 17, 1952, to Secretary to the Board, Royal Infirmary Branch, Bristol, 2. (8772)

Applications are invited from qualified medical practitioners for this post, and must be received not later than March 22, 1952. Preference will be given to applicants holding the D.P.H. Salary £850 by £50 to £1,150, commencing salary according to qualifications and experience. Canvassing is prohibited. Candidates must disclose relationship to any member or officer of the Council. Further particulars can be obtained from me.—W. Staley Brookes, Town Clerk, The Council House, Walsall. (8869)

Public Health—contd.**WORCESTERSHIRE COUNTY COUNCIL
BOROUGH OF OLDBURY
OLDBURY BOROUGH MEDICAL OFFICER OF
HEALTH AND WORCESTERSHIRE COUNTY
DIVISIONAL MEDICAL OFFICER AND
SCHOOL MEDICAL OFFICER**

Applications are invited from qualified and duly registered medical practitioners, men or women, holding the Diploma in Public Health and possessing the requisite experience. The salary will range from a minimum of £1,491 13s. 4d. to a maximum of £1,858 6s. 8d. (namely the Borough Medical Officer of Health post will be on the scale of £516 13s. 4d., rising by annual increments of £16 13s. 4d. to a maximum of £583 6s. 8d., and the Divisional Medical Officer post on the scale of £975 by annual increments of £37 10s. to a maximum of £1,275 per annum). The post is superannuable, subject to medical examination and determinable by three months' notice. The successful candidate will be required to reside in the Divisional Area. He will be required to undertake such duties as may be assigned to him and will be precluded from undertaking any other duties except with the Council's previous consent. Travelling allowance for the use of the officer's own car will be paid in accordance with the County scale. Application forms from County Medical Officer, County Buildings, Worcester, to be returned not later than March 12, 1952.—Kenneth Pearce, Town Clerk, Municipal Buildings, Oldbury; W. R. Scurfield, Clerk of the County Council, Shirehall, Worcester. (X104). (8606)

GOVERNMENTAL**TREASURY MEDICAL SERVICE**

Applications are invited from medical practitioners, practising in the districts detailed below, for appointment, in a part-time and mainly advisory capacity, as

LOCAL TREASURY MEDICAL OFFICER

for each of the places or groups of places shown. The town shown in brackets after the place-names indicates the Head Post Office Area in which the place, or group of places, is situated. Successful applicants will be required to examine and report on the condition of certain Government officers, teachers, candidates for appointment, etc., who may be referred to them from time to time; and to attend when summoned to an emergency case of accident or sudden illness occurring in a Government office in the neighbourhood. Fees for this work, and mileage allowance where necessary, will be paid on a scale agreed with the British Medical Association. Intending applicants should write, within fourteen days, to Treasury Medical Adviser, Treasury Chambers, Whitehall, S.W.1, for a form on which application may be made. Applicants should be not more than 60 years of age.

The places for which applications are invited are as follows:

England and Wales

Plymouth (Plymouth).
Rotherham (Rotherham).
Sale (Manchester).

Northern Ireland

Pomeroy (Dungannon).
Coleraine (Coleraine).

(8884)

SERVICES**ROYAL NAVAL MEDICAL SERVICE**

Candidates are invited for service as
MEDICAL OFFICERS

in the Royal Navy—preferably below 28 years. They must be British subjects whose parents are British subjects, and be medically fit. No examination will be held, but an interview will be required. Initial entry will be for four years' short service, after which gratuity of £600 (tax free) is payable, but permanent commissions are available for selected short service officers. Officers entered on or after January 1, 1951, will be eligible to be considered for antedates of seniority up to two years for service in recognized civil hospitals, etc. For full details apply Medical Director-General, Admiralty, S.W.1.

COMMERCIAL APPOINTMENTS

IMPERIAL CHEMICAL INDUSTRIES, LIMITED, requires a woman graduate to undertake maintenance and development of a scientific bureau of medical, toxicological and technical information in their Industrial Hygiene Department at Welwyn. Useful subject, chemistry and biology. Knowledge of medical terminology and some languages an advantage. Post is graded Assistant Technical Officer. Write for application form to Personnel Officer, I.C.I. Ltd., The Frythe, Welwyn, Herts.

INDUSTRIAL APPOINTMENTS**FACTORY DOCTORS
FACTORIES ACTS, 1937 and 1948**

The following appointments as Appointed Factory Doctor under the Factories Acts, 1937 and 1948, are vacant: Plymouth, in the County of Devon; Rotherham, in the County of York. Applications, which should be received not later than March 15, 1952, should be sent to the Chief Inspector of Factories, 8, St. James's Square, London, S.W.1.

MAJOR U.K. OIL COMPANY REQUIRES TWO full-time Medical Officers—one to be located in London, and the second in Manchester. The London post will involve mainly clinical work, and the doctor appointed should have good clinical experience and be well qualified. The Manchester post, in addition to clinical duties, will include some general industrial work, and experience and interest in organization and preventive medicine will be an advantage. Commencing salary in both cases within the B.M.A. scale for Industrial Medical Officers, and dependent upon experience, qualifications, etc. Apply as soon as possible, giving full details of qualifications, experience, and names of two referees, to Box 809, B.M.J.

MONSANTO CHEMICALS, LIMITED, INVITE applications from registered medical practitioners (male) for the full-time post of Medical Officer at the Ruabon factory. The duties will embrace the normal functions of an industrial medical officer, and the successful candidate will be responsible for the medical and first-aid services in the factory. Candidates should have a good standard of clinical medicine and an interest in preventive and industrial medicine. Previous industrial experience not essential. Commencing salary, according to age, experience, and qualifications, but not less than £1,100 per annum. Generous pension and superannuation scheme. Applications in the first instance should be made in writing to the Chief Personnel Officer, Monsanto Chemicals, Ltd., Allington House, Allington Street, London, S.W.1. (8870)

EIRE**GALWAY COUNTY COUNCIL**

Applications are invited for the following posts in Galway Central Hospital:

- (a) SENIOR RESIDENT MEDICAL OFFICER
(b) SENIOR RESIDENT OBSTETRICAL OFFICER

for a period of six months in the first instance as from April 1, 1952. Remuneration in each case at the rate of £200 per annum, with rations, apartments, fuel, light, laundry and attendance, together with temporary bonus of £41 18s. per annum. Applicants must be not less than 24 years of age on March 1, 1952, and must have had twelve months' experience in a hospital as a Resident Medical Officer, six months of which must be gained in the post of Resident House Physician in a general hospital. In the case of (b) candidates should possess the L.M. Diploma (postgraduate) granted by one of the Dublin Maternity Hospitals, or qualifications equivalent thereto.

(c) JUNIOR RESIDENT HOUSE PHYSICIAN for six months as from April 1, 1952.

(d) JUNIOR RESIDENT HOUSE PHYSICIAN for six months as from May 1, 1952.

Remuneration in each case at the rate of £150 per annum, with rations, etc., plus temporary bonus of £41 18s. per annum. Applicants must be not less than 23 years of age on March 1, 1952.

Applications, stating date of birth, together with certificate of registration, testimonials and certificates of experience, should be lodged with the Secretary, Galway County Council, County Buildings, Galway, on or before March 8, 1952. (8906)

**JOINT COMMITTEE OF MANAGEMENT OF
CORK SANATORIA**

Applications are invited for the temporary post of
RESIDENT SURGICAL OFFICER

at Mallow Chest Hospital. Remuneration will be at the rate of £350 per annum, together with board, residence, laundry, and emergency bonus, which at present is at the rate of £60 per annum. Completed forms should be lodged not later than 12 noon on Tuesday, March 11, 1952, with the undersigned, from whom application forms and further particulars may be obtained.—D. O'Donovan, Secretary, Monument Buildings, 42, Grand Parade, Cork. (8871)

ALBANY HOSPITAL, Albany, N.Y.

Internships and residencies available in Albany Hospital, Albany, New York. 750-bed, general hospital, directly associated with Albany Medical College. House officers receive appointments in medical school. Salaries range from a minimum of \$300 a year for interns to \$1,400 a year for residents. Details on request. (9695)

HER MAJESTY'S COLONIAL SERVICE, Malaya

Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom with one or more years' experience after qualification are required for appointment as
MEDICAL OFFICERS AND MEDICAL OFFICERS OF HEALTH

for General Medical and Health duties

Appointment is available (a) on probation for permanent establishment; (b) on employment from the National Health Service; and (c) on short-term contract with gratuity. (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale £952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). Note. Doctors with more than one year's approved experience after age 25 (including service in Her Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g., F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malaya salary on leaving Malaya at the end of their engagements. Emoluments as under (a), including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a) including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity refer to doctors eligible for expatriate terms under Malayan Regulations (i.e., those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan Medical Service. The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates, which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/242/51). (5187)

Overseas—contd.

AUCKLAND HOSPITAL BOARD, N.Z.

Applications are invited from those with the necessary qualifications for the status of Junior or Senior Specialist for the position of

RADIOLOGIST, Board's Institutions

Applicants must be qualified medical practitioners of the British Commonwealth, and the appointee shall be registered in New Zealand before taking up duty. Salary, Junior Specialist £1,260 per annum, rising to £1,560 per annum by annual increments of £50. Senior Specialist £1,660 per annum, rising to £1,910 per annum by annual increments of £50. Commencing salary within these scales will be in accordance with qualifications and experience in the specialty. The amounts quoted are in New Zealand currency and are living out rates. Living accommodation is not provided. Particulars regarding payment by the Board of travelling expenses are set out in the conditions of appointment which, together with an application form, may be obtained from the Office of the High Commissioner for New Zealand, 415, Strand, London, W.C.2. Applications, addressed to the Secretary, close at the office of the Board, Kitchener Street, Auckland, New Zealand, at noon on Monday, April 7, 1952. (8487)

FREMANTLE GENERAL HOSPITAL (200 beds)
Western Australia

Applications are invited from registered medical practitioners for the non-resident appointment of

ANAESTHETIC REGISTRAR

Successful applicants must have had at least two years' experience since graduation. Preference will be given to applicants holding the Diploma in Anaesthetics. The term of appointment will be by mutual arrangement, but it is desired that the term be not less than three years. The salary range will be from £A.1,183 to £A.1,433, according to experience. An allowance of a maximum of £120 (Sterling) will be made available towards the cost of transport. Applications, in duplicate, stating full name, date, and place of birth, qualifications, and experience, conjugal conditions, and indicating the earliest date upon which the applicant could take up duty, should reach the Agent General for Western Australia, Savoy House, 115, Strand, London, W.C.2, from whom further particulars may be obtained, not later than March 15. (8806)

PRINCESS TSEHAI MEMORIAL HOSPITAL
AND SCHOOL

P.O. Box No. 1377, Addis Ababa, Ethiopia
Applications are invited from British-born medical practitioners for the following appointments:

ANAESTHETIST (D.A.)

Three years' contract with the Ethiopian Government at a salary of Ethiopian dollars 15,000 per annum (£S.7 equals £1 sterling). Return air passage provided for self and wife. Half month's salary as travelling allowance and two cubic metres baggage by sea route. Partially furnished quarters free. Successful candidate will be expected to serve other hospitals in Addis Ababa, the necessary transport being provided. Leave, one month per annum accumulative and two weeks' per annum local leave. Schooling is adequate for young children. Climate temperate at 8,500 feet.

RADIOLOGIST (D.M.R.)

Conditions of service, salary, etc., as for the above appointment.

Applications for either appointment, stating age and experience, together with copies of three recent testimonials and health certificate, should be sent immediately by air mail to Colonel W. Byam, O.B.E., Director. (8805)

UNIVERSITY OF OXFORD

Election of one member of the Board of the Faculty of Medicine by the General Medical Electorate

An election of one member of the Board of the Faculty of Medicine (vice Mr. E. A. Crook, who is re-eligible) will be held on Wednesday, June 4, 1952. The member elected will hold office for two years from the first day of Michaelmas Term, 1952. The General Medical Electorate consists of all Oxford Graduates in Medicine who are members of Convocation. The Board of the Faculty of Medicine includes two members elected by the General Medical Electorate who must be members of that body and of whom one at least must be a person engaged in teaching one or more of the clinical subjects of the Faculty. The other member elected by the General Medical Electorate is Sir J. J. Conybeare, K.B.E. Nominations of duly qualified candidates for election will be received by the Secretary of Faculties at the University Registry up to 10 a.m. on Wednesday, May 7, 1952. Each nomination must be signed by six members of the General Medical Electorate, and no candidate will be eligible whose nomination has not been received by that date. (8771)

POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS. Examination successes: 1938-1951: M.D.Lond., 65; M.B., B.S.Lond., Final, 152; F.R.C.S.Eng., Primary, 197; F.R.C.S.Eng., Final, 185; M.R.C.P.Lond., 204; M.R.C.S., L.R.C.P., Final, 331; D.A., 181; D.C.H., 139; M. and D.Obst.R.C.O.G., 221; D.O., C.P.H., D.P.H., D.L.O., D.P.M., F.R.C.S.Edin., many successes. Assistance with M.D. Thesis. Prospectus, list of tutors, etc., on application to Dr. G. E. Oates, University Examination Postal Institution, 17, Red Lion Square, London, W.C.1. Phone: HOLborn 6313.

ROYAL COLLEGE OF SURGEONS OF ENGLAND
RESEARCH SCHOLARSHIP

A Leverhulme Research Scholarship will shortly be awarded by the Royal College of Surgeons of England. The Scholarship is of the annual value of £400, with an allowance not exceeding £100 for expenses of research, tenable for one year in the first instance, but renewable at the discretion of the Council. Scholars may be male or female, and must hold a medical qualification registrable in the United Kingdom or a university degree. Scholars must devote themselves to the investigation of some biological or clinical problem of disease as it occurs in man, with a view to the extension of surgical knowledge. Facilities for research will be provided in the Bernhard Baron laboratories of the Royal College of Surgeons in Lincoln's Inn Fields, or at the Buckton Browne Farm, Downe, Kent. In special circumstances Leverhulme scholars may work elsewhere. Applications, stating the nature of the proposed research and accompanied by a recommendation from a member of the staff of the applicant's medical school or university, should be sent to the Secretary, Royal College of Surgeons, Lincoln's Inn Fields, W.C.2., on or before March 12, 1952.—Kennedy Cassels, Secretary. (8876)

ROYAL COLLEGE OF SURGEONS OF ENGLAND

SURGERY LECTURES AND CLINICAL CONFERENCES, APRIL AND MAY, 1952

A Course of 24 Surgery Lectures, with ten clinical conferences at certain selected hospitals, will be held from April 15 to May 2, 1952. Only a limited number of students can be accepted for the conferences. Fees: Whole Course, £12 12s.; Lectures only, £8 8s. Applications, accompanied by a cheque for the appropriate fee, should be sent to W. E. Davis, Esq., Deputy Secretary, Royal College of Surgeons of England, Lincoln's Inn Fields, W.C.2., from whom further information may be obtained (HOLborn 3474). (8875)

SOCIETY OF APOTHECARIES OF LONDON.

Surgery: April 15, May 12, June 9. Medicine and Pathology: April 21, May 19, June 16. Midwifery: April 22, May 20, June 17. Mastery of Midwifery: May and November. Diploma in Industrial Health: July and December. For regulations apply Registrar, Apothecaries' Hall, Black Friars' Lane, London, E.C.4.

SURGICAL REVISION (F.R.C.S.), MONDAY.

Thursday and Friday mornings, March 10 to April 26. Royal Cancer Hospital. Apply Fellowship of Postgraduate Medicine, 60, Portland Place, London, W.1. Langham 4266.

TUBERCULOSIS EDUCATIONAL INSTITUTE

A three-day Clinical Course will be held at the Red Cross Sanatoria of Scotland (Tor-na-Dee and Glen o'Dee) on March 19, 20, and 21. Fee £3 3s. Applications to the Secretary, Tuberculosis Educational Institute, Tavistock House North, Tavistock Square, London, W.C.1. (8488)

ROYAL COLLEGE OF SURGEONS OF ENGLAND

* Candidates must hold a medical qualification registrable in this country.

† Candidates must be Fellows or Members of the College.

Forms of application can be obtained from the Secretary, and these must be completed and returned by Friday, March 21, 1952.

KENNEDY CASSELS,
Secretary.

Lincoln's Inn Fields, London, W.C.2.
March, 1952.

LECTURES

UNIVERSITY OF LONDON.—A LECTURE ON "Interactions of Proteins with Ions and Neutral Molecules" will be given by Dr. J. T. Edsall (Harvard) at 6 p.m. on March 12, 1952, at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C.1. Admission free, without ticket.—James Henderson, Academic Registrar. (8877)

UNIVERSITY OF LONDON.—A LECTURE ON "The Cerebellum and its Connections in the Light of Recent Investigations" will be given by Professor J. Jansen (Oslo) at 5 p.m. on March 6, 1952, at St. Mary's Hospital Medical School (Wright Fleming Institute Lecture Theatre) Paddington, W.2. Admission free, without ticket.—James Henderson, Academic Registrar. (8878)

SITUATIONS VACANT

North Devon Hospital Management Committee.—Pathological Laboratory, Bampton Street, Barnstaple. —Applications are invited for the post of Technician or Junior Technician in a new laboratory serving the North Devon District. Considerable experience in haematology is essential. Salary and conditions in accordance with Whitley Council scales. Applications, stating age, qualifications and experience, together with the names of two referees, to the Pathologist at the above address. (8108)

Ferrous Gluconate

A Major Advance in the Field of Oral-Iron Therapy

... is presented in ELIXIR CEREVON in combination with the important Vitamin B factors, aneurine hydrochloride, nicotinamide and riboflavine. Ferrous Gluconate possesses advantages over ferrous sulphate in that it is more readily absorbed by the stomach and utilized by the haemopoietic system, without giving rise to gastric disturbance, even in patients who have shown intolerance to other forms of iron.

The high palatability of ELIXIR CEREVON is provided by 15% natural blackcurrant juice with glucose, which assists absorption and provides each teaspoonful of the Elixir with at least 5 mgm. Vitamin C.

INDICATIONS:

Secondary anaemias of pregnancy and malnutrition and as a reconstructive tonic.

FORMULA:

Ferrous Gluconate ..	0.3 gm.
Aneurin. Hydrochlor. ..	1 mgm.
Riboflav. ..	1 mgm.
Nicotinamide ..	10 mgm.
With trace elements of Copper and Manganese.

ROBINSON'S

Robsoup

**THE NEW WEANING FOOD
FOR BABIES**

ROBSOUP is a concentrated bone and vegetable soup, ready cooked in powder form. The food constituents are different from and complementary to those of milk mixtures and cereals.

Robsoup mixes instantly with water at all temperatures to any consistency from a thin broth, suitable for adding to the baby's bottle, to a thick soup which may be fed from cup and spoon.

Robsoup is simple to use and economical—a 1/6d. tin gives ten helpings for a baby of five months. There is no waste with Robsoup. Only the amount required for the next meal is mixed at any one time. Being a dry powder, what is left in the tin will not go bad.

Therefore, provided the water used for mixing has been boiled and the cup and spoon are clean, Robsoup is safe from the danger of food infection and will not occasion gastro-enteritis.

Robsoup is made by a new process from peas, potatoes, carrots, yeast extract, cabbage, gelatin, edible bone phosphate, salt and onion. It is rich in iron (12 mg. per 100 gms.), calcium (400 mg. per 100 gms.) and vegetable protein (15.5%). Robsoup may therefore be given either as the first addition to milk or as the next step in weaning after the introduction of a cereal. Extensive tests have shown that babies thrive on Robsoup and like its flavour.

Ph.239

Doctors, matrons and other hospital authorities have noticed that patients are more comfortable, more relaxed, as soon as they are placed on an Intalok mattress. The reason is shown in the illustration.

The background photograph shows a top-view section of an Intalok mattress. Each fine gauge spring is loosely interlinked with the next, throughout the whole length and breadth. The surface coils yield to first pressure—and as weight increases, many other springs combine to take the weight. The diagram shows what this scientific springing does, under the weight of the patient. The compression varies exactly with the contours of the body. Where weight is heaviest compression is unusually deep. There is no excessive resistance to cause aching or soreness to pressure points. The patient, in any position, is correctly and naturally supported. Thus there is no sagging, less tendency for the body to slip. The patient enjoys an exceptional degree of comfort on Intalok.

Here are other good reasons why hospital authorities are in favour of Intalok mattresses :

- 1 *The mattresses can be stoved; in fact they gain by stoving.*
 - 2 *All metal parts are rustless, can be sterilized repeatedly.*
 - 3 *Intalok mattresses have no tufts or piping to collect dust and germs.*
 - 4 *The ticking is easily removable for laundering.*
 - 5 *Existing hair mattresses can be converted to Intalok—the good hair being retained. This cuts costs.*
 - 6 *Every Intalok springing unit is guaranteed for 10 years.*
- Write today for illustrated leaflet and prices.*

Labels: (a) Labeling provision must be strictly worked on the manufacturer's or purchaser's weight in relation to the label and (b) the number of the lot or batch must be clearly marked on the label and the label must be clearly marked with the name of the manufacturer.

Non-traumatic suturing, reliability in tensile strength and thus the simplification of operating technique coupled with satisfactory surgical results, are all governed largely by correctly gauged material.

Ethicon accepted the challenge laid down by the Codex Revision Committee in 1949. By "continuous" gauging along the whole strand, by calibrating gauges every two hours, by making allowances for diameter changes due to processing and reconditioning and by carefully controlled tensile strength tests, Ethicon has placed in the hands of the surgeon through his theatre sister, the catgut on which he can rely day in and day out. Ethicon have tried hard to fulfil their responsibility to the profession by making available an ever increasing quantity of first grade gut acceptable to the highest British standards in surgery.

LONDON SATURDAY MARCH 8 1952

CORONARY HEART DISEASE IN MEDICAL PRACTITIONERS

BY

J. N. MORRIS, M.R.C.P., D.P.H.

J. A. HEADY, M.A.

(From the Medical Research Council's Social Medicine Research Unit, Central Middlesex Hospital)

AND

R. 'G. BARLEY, F.I.A.

Assistant Actuary of the Medical Sickness, Annuity and Life Assurance Society, Ltd.

In a previous paper some aspects of the recent history of coronary disease were examined. The evidence given there supported the widely held view that there has been some true increase of coronary thrombosis and coronary heart disease during the present century, apart from the effect of the ageing of the population, and it was suggested also that this increase may not have been due to an increase of the underlying chronic atheroma (Morris, 1951). The present report turns to the contemporary situation, and gives some results of an inquiry on coronary heart disease carried out in various occupations.

There is no doubt that coronary heart disease is a major problem of the public health, and, however the certified causes of death are regarded, coronary heart disease must now be among the commonest. Little is known about its causes, and experience of other conditions suggests that examination of the epidemiology may well be rewarding. There are indications, also, from clinical experience and the figures of the Registrar-General, of social factors in coronary heart disease, in work and mode of life, and these clues must be followed up. If coronary heart disease is in fact commoner than it used to be, environmental changes with which the increase may be associated must be sought, however indirectly such changes may seem to operate.

An investigation has been conducted in several occupational groups; and the results of this study in one group, medical practitioners, are now being given because the information was obtained in a special way and because it is likely to be exceptionally reliable. There is some general feeling, too, that doctors may suffer more than others from coronary heart disease, and the present figures may give some idea, at least, of the "ceiling" of this disease in the population. This occupation, moreover, though of particular interest, is amongst the least studied.

Material and Methods

The present study was made from the records of the Medical Sickness, Annuity and Life Assurance Society, Ltd. (after this called "the Society"), a mutual benefit organization which has several thousand doctors on "non-cancellable" sickness and accident policies (Heath, 1939). "Non-cancellable" indicates a form of insurance in which renewal is not subject to annual review by the

Society, and continuance of the policy is thus independent of morbidity experienced while holding the policy. The Society's records of the later attacks of a disease, therefore, are as representative as its records of the first attacks. Most policies issued provide for payment of a weekly benefit from the outset of any sickness, or accident, causing total incapacity to carry out the member's occupation for seven days or longer. The inquiry was limited to the records of members holding these "immediate benefit" policies, since the records of other policies providing "deferred benefit" do not give full information concerning the early part of a period of incapacity. The Society's policies in general terminate at age 60 or at age 65 years, and the present inquiry is restricted to ages 35-64 years, inclusive. Males only were studied because of the small number of women in the Society in the age groups most important to this inquiry. Throughout the report, therefore, when "medical practitioners" or "doctors" are mentioned, reference is intended to male members of this Society, of the ages stated, holding the relevant insurance—and to no others.

The "population" being studied, although it is substantial and may include about a quarter of the country's doctors in the ages considered, is *selected*, because a full medical examination is given to all applicants. It is possible, therefore, for instance, that doctors who know they have diabetes or material hypertension may hesitate even to apply for insurance. The great majority of policy-holders, however, join in their late twenties and early thirties—that is, before coronary heart disease, or the conditions with which it may be associated, can usually be recognized. Such selection as this is likely to be in the "safe direction" for the present inquiry, for it will reduce the number of cases found, and not exaggerate it. There is no information on which to base discussion of the more subtle selective factors. Is it the more anxious personality who applies for a policy? Or the more careful? Or the man who is less careful but who knows himself to be so, and wishes to protect his dependants from the risks he cannot stop himself taking? Does an unhealthy family history prompt the taking out of insurance? There is even less basis on which to discuss the unconscious motivation involved. The mortality of members of this Society cannot be compared with that of all "physicians and surgeons, etc.," reported in the Registrar-General's occupational

mortality supplement for 1930-2 (Registrar-General, 1938), because the age structure of the Society's membership during those three years is unknown.

Payment of benefit is on the basis of medical certificates which involve at least two doctors—the patient and his medical attendant. Although a "specialist opinion" is not of course necessary, examination of a large proportion of the records of first illness from coronary heart disease showed that such confirmation of the diagnosis had, in fact, been recorded in three-quarters of the cases, often with copies of electrocardiographic findings, etc. As a routine precaution all the certificates for each illness were considered and the final diagnosis was used. The recording was carried out with a combination of serial numbers and names, which permitted the fullest use of the available information, and at the same time preserved the confidential nature of the records. All deaths of members are known to the Society, including coroners' cases, and a copy of the death certificate is obtained.

Coronary heart disease in the present inquiry includes the following disorders arising on atheroma of the coronary arteries, with thrombosis, obstruction, occlusion: the clinical syndromes usually called "*coronary thrombosis*" (*sudden deaths* and *myocardial infarction*); *angina pectoris* (or of effort); and occasional cases described as "*coronary insufficiency*," etc. Cases diagnosed as "*angina pectoris*," without a pathology being stated, were also included. "*Ischaemic heart disease*" is the more accurate term, but "*coronary heart disease*" is convenient and in too common use to be discarded. Throughout the paper reference is intended only to the above *clinical* manifestations of the disease, together with their complications and consequences, and not at all to the natural history of the disease in *pathological* terms. "First attack," for example, and "first clinical attack" are used interchangeably.

Apart from the main statements on the certificates, referring in the present instance to coronary heart disease, further information was often given—for example, on hypertension and other associated conditions. No particular attention, however, can here be paid to these. The present type of study, moreover, is not suitable for the consideration of such clinical matters as the site of infarction. The mortality analysis, similarly, deals only with coronary heart disease as the certified cause of death; often there was evidence of necropsy, but this aspect had also to be ignored.

In summary, therefore, information about the male members of the Society aged 35-64 years who hold immediate benefit non-cancellable sickness insurance, and are absent from work because of coronary heart disease, is available as follows: *Where the absence lasts less than a week*: Information only about *deaths*, from death certificates (and, often, other reports). *Where the absence lasts a week or longer*: Information on medical certificates about the *illness*, from the *first* day of the absence. Date of ending of *absence*, as well as its beginning. Information about *deaths* as above.

Figures will be presented for *morbidity* and *mortality*. The annual rates of occurrence of various manifestations of the disease at different ages will be worked out in the usual way, by reference to the total number of men concerned—for example, if over a given period there is an average of 12 cases a year (the "numerator") in men aged 50-54 years, and over the same period an average "population" of 1,500 doctors of that age with non-cancellable insurance (the "denominator"), the *average annual rate* is 8 per 1,000.

Since *comparison of rates* in two population groups can be misleading if one group includes more old people than the other, the rates in this paper which summarize the experience of men over a wide age range—for example, 40-59 years—will be *standardized* for age. The "standard" population that will be used here is the civilian population of England and Wales in mid-1949, the latest figures available at the time from the Registrar-General.

PART I: THE DISEASE IN MEDICAL PRACTITIONERS

Incidence

The "incidence" gives the number attacked by coronary heart disease for the first time, so far as is known, in 1,000 of these medical practitioners per year. The number of new cases is a basic figure to have in studying disease in any "population," whether it is this group of doctors or one doctor's practice. As used here, the "incidence" is the rate of all first manifestations of coronary heart disease, regardless of the form taken, that (a) were recognized and diagnosed among these medical practitioners, and (b) led to absence from work lasting a week or more, or to death. The attack was regarded as a first attack if there had been no previous claim for benefit for coronary heart disease.*

Column 1 of Table I shows the ages; column 2 the average number of practitioners holding the relevant insurance

TABLE I.—Incidence of Coronary Heart Disease in Medical Practitioners, 1947-50. Men Aged 35-64 Inclusive. Average Annual Rates per Thousand

Ages Last Birthday (Years) (1)	Mean Population (2)	No. of First Attacks (3)	Incidence—First Attack Rate p.a. (4)
35-39	1,155	2	—
40-44	1,367	12	2.2
45-49	1,549	21	3.4
50-54	1,006	28	7.0
55-59	696	33	11.9
60-64	407	27	16.6
All ages 35-64 incl.	6,180	123	5.0
Standardized rate at ages 40-59 incl.			5.5
" " " " 40-64 "			7.1

Ages.—All recording was based on year of birth. Ages are therefore in fact ages attained at the beginning of the calendar year.

Mean Population.—This was calculated from annual counts of the Society's membership, as on January 1 of the five years 1947-51. All men included held non-cancellable sickness and accident insurance, at the date of the count, of a type providing benefit from the beginning of periods of absence from work because of sickness which lasted seven days or more. The members of the Society are mostly resident in the United Kingdom, though there are a few elsewhere.

First Attacks.—These are men clinically attacked by coronary heart disease (as defined) for the first time between January 1, 1947, and December 31, 1950, who, at the time of this attack, held insurance of the type above. The figure are made up of (a) non-fatal first attacks causing absences from work for seven days or more, and (b) all fatal first attacks.

Incidence.—First attacks per 1,000 living, per annum.

Standardized Rates.—These are based on the civilian population of England and Wales in mid-1949.

*It is not possible to be absolutely certain that first claims for coronary heart disease always represented first absences for this condition, or that first absences always coincided with the first diagnosis, or first diagnoses with first clinical attacks. Diagnoses may be missed, and atypical and premonitory cardiac pain, for instance, may be overlooked. It is conceivable, too, that *angina pectoris*, even when diagnosed for the first time, and even among medical practitioners, did not always lead to as much as a week's sick leave. It is not possible, however, to check this kind of matter, and since it is unlikely that such reservations could be common enough to affect the age or other trends being investigated, they will be ignored. The further possibility that practitioners may have taken time from work, and not troubled to claim the benefit to which they were entitled, is also not likely to have modified the results. The Society's experience of claims made retrospectively is that such claims have rarely to be made for illnesses which have lasted any length of time. Eighty per cent. of observed first absences for *angina pectoris*, and 97% of observed first absences for "*coronary thrombosis*" (that was not rapidly fatal) lasted more than a month. The *average* first absences were, of course, much longer. In brief, it is considered that the chain of events, first diagnosis of coronary heart disease—sick absence for a week or longer—claim for benefit, is reasonably complete. The "*sudden*" deaths are in a different category, and are covered.

in each age group over the four years 1947-50; column 3 is the number of first attacks recorded in the four years; and column 4 gives the "incidence"—the annual rate of first attack per 1,000 in each age group. Column 4 shows a steep incline from the late thirties to 16.6 per 1,000 among men in their early sixties (Fig. 1).

FIG. 1.—Incidence and mortality in coronary heart disease, 1947-50. Male medical practitioners aged 40-64 inclusive. (See notes to Tables I and II for information about the Society's membership, etc.)

Mortality Rates

Coronary heart disease is the main "cause of death" in the Society after 35 years of age, about one-third of all mortality among members being ascribed to it, and this fraction does not vary with age. Under, say, 50 years this fraction will be influenced by the Society's policy of selection, but after about 50 it may represent a more complete picture of the experience of medical practitioners. Table II includes all the "coronary" deaths in the population described in Table I. Columns 2, 4, and 6 give the number of deaths; columns 3, 5, and 7, in italics, the relevant rates.

TABLE II.—Mortality from Coronary Heart Disease in Medical Practitioners, 1947-50. Men Aged 35-64 Inclusive. Average Annual Rates per Thousand

Ages Last Birthday (Years)	Deaths in First Six Days of First Attack		Deaths in First Month of First Attack		All "Coronary" Deaths	
(1)	No. (2)	Rate (3)	No. (4)	Rate (5)	No. (6)	Rate (7)
35-39	1	—	1	0.9	2	0.9
40-44	9	0.8	6	1.0	8	1.3
45-49	14	2.1	5	1.2	8	2.0
50-54	5	3.1	12	4.3	13	4.7
55-59	5	3.1	9	5.5	12	7.4
60-64	5	3.1	9	5.5	12	7.4
35-64 incl. ..	29	1.2	38	1.5	48	1.9
40-59 "	23	1.4*	28	1.7*	34	2.0*
40-64 "	28	1.6*	37	2.2*	46	2.8*

* Standardized rates.

For notes on ages, the Society's population, and standardized rates, see Table I.

Columns 4 and 5: Lengths of sick absences were calculated in years to 2 decimal places. Deaths in the first "month" were taken to be those occurring in 0.08, or less, of a year.

Columns 6 and 7: All deaths ascribed to coronary heart disease, as defined. The rates of column 7, Table II, may be compared with the American rates for 1938-42:

Mortality From Coronary Heart Disease in Medical Practitioners of U.S.A.

Age	Rate	Age	Rate
35-39 ..	0.37 per 1,000	50-54 ..	3.76 per 1,000
40-44 ..	1.02 ..	55-59 ..	5.92 ..
45-49 ..	1.79 ..	60-64 ..	8.03 ..

(Dublin and Spiegelman, 1947; Dublin, 1951).

Columns 2 and 3 deal with the deaths occurring quickly and referred to throughout this report as "sudden." The exact duration of the illness in the present series of "sudden" deaths cannot be specified. No benefit is paid for absence lasting less than seven days; and in these cases, since the question of a claim for sickness benefit does not arise, there is no obligation on the relatives or executors to state how long the illness lasted, or on the Society to ask for the information. Though it is known that in the majority the death occurred very quickly, it can only be stated of them all that they occurred within six days of the onset of illness causing incapacity to work. The "sudden" death rate, column 3, rises to 3.1 per 1,000 at 60-64 years of age. Columns 4 and 5 of Table II include all deaths occurring in the first month of the clinical disease; the rate rises to 5.5 at 60-64 years. Columns 6 and 7 represent all deaths certified as due to coronary heart disease in these practitioners (Fig. 1). This rate reaches 7.4 per 1,000 at 60-64 years.†

The main fact that emerges from Table II is the predominance of the first clinical attack, even as represented here only by the first month of absence from work, in the total mortality from coronary heart disease in these men under 65 years of age. About 80% of the mortality at 40-64 from coronary thrombosis, myocardial infarction, and their consequences, in 1947-50, occurred in the first month (cf. columns 5 and 7 of Table II). Sixty per cent. of the total coronary mortality rate represented the deaths occurring, as described, very quickly in the first few days of the first clinical attack—standardized rates of 1.6 per 1,000 in column 3 and 2.8 per 1,000 in column 7. (The Society's experience of 1940-6 was similar enough to that of 1947-50 for the deaths of the 11 years 1940-50 to be amalgamated in Fig. 2.) If this figure of 55 or 60% is at all typical of

FIG. 2.—Deaths from coronary heart disease occurring in 1940-50. Male medical practitioners aged 40-64, inclusive. There were 104 coronary deaths in these members during the 11-year period.

what is happening in the general population in the coronary heart disease of middle age, it sharply focuses the gravity of the "acute" phases of this "chronic" disease, and points very clearly to the time of greatest need for therapy—the first few days of the first clinical attack of "coronary thrombosis." The size of this figure is interesting for two other reasons: it reinforces the conviction formed during the earlier investigation (Morris, 1951) that cardiac pathology cannot be studied properly to-day unless there is the closest relationship between the hospital and the coroner's court, especially if the hospital cannot, or does not, provide

†Gosse (1942) made a study of material from the same source, in which he paid attention to the mortality from coronary heart disease among the medical profession. In wartime conditions it was not possible for the Society to construct the considerable subsidiary recording system necessary to produce the results here published. In particular, the Society's normal records in some respects concern policies rather than lives, and many members have more than one policy. Much of the labour involved in the present inquiry has been spent in ensuring that information based on policies has been properly allocated to lives. It follows that the analyses in this paper cannot be compared directly with the broader figures given by Gosse, and no attempt has been made to do so.

facilities for the B(rought) I(n) D(ead). The size of this fraction may also explain some of the variation in the mortality rates reported in hospital series of "coronary thrombosis" (McCain, Kline, and Gilson, 1950; Tulloch and Gilchrist, 1950). If hospitals have an open door for all types of "emergencies" they are more likely to admit these men who will die in the first few days, with consequences in their statistics. Hospitals having a different admission policy may see few such patients, and show much "better" mortality rates, though the general practitioners and coroner's pathologists of the district may find the rates surprising.

Before leaving these morbidity and mortality figures it may be mentioned that there was no particular concentration of first attacks or of deaths in any part of the year, though the April-June quarter had the lowest numbers.

The Individual Practitioner's Chances

What are the chances that members of the Society will develop coronary heart disease, and die of it, should current attack and mortality rates continue? The numbers in the present inquiry are small, but the rates (Tables I and II) progress with sufficient regularity to justify an attempt to answer these questions. Appendix 1 sets out the details of the methods adopted: here it need only be said that a "life table" approach was made. To estimate the chances of getting the disease before age x , the rates of first clinical attack at different ages under x are used; and the resulting numbers attacked at each age are summed. These rates, however, are not quite the same as in Table I, because the present calculations are concerned only with the incidence among those who have not yet had the disease, and are thus "eligible" for a first attack, whereas Table I deals with all who are alive at particular ages. Moreover, there is some evidence in the four years' material of an increase in the occurrence (or recognition) of non-fatal first attacks in 1949-50, compared with 1947-8, and, as the basis of the probabilities being estimated is the current frequency of the disease, the incidence rates were therefore recalculated for 1949-50. To estimate the chances of dying from coronary heart disease before any particular age x , the chances at individual ages under x are similarly calculated and brought together. In this instance the "eligibles" are all those who are alive, because those who have had the disease before are very much exposed to the risk of dying of it; and the mortality rates of Table II were used because there was little difference in the mortality experience of 1947-8 and of 1949-50.

Table III shows the probability that these medical-practitioner members of the Society, not as yet suffering from clinical coronary heart disease, will be attacked before particular ages. If present rates of incidence continue, it can be seen by reading horizontally along the bold figures that, of 1,000 men aged 35, three may be expected to develop the disease in the next five years—that is, before they are 40, another seven by 45, and so on. Of 1,000 aged 60, 90 will

TABLE III.—Chance of Getting Coronary Heart Disease

The number of male medical practitioners who, not having previously been clinically attacked by it, would get coronary heart disease before reaching certain ages.

Age x (Years)	Of 1,000 Men Aged x , the Number Indicated Below Would Get Clinical Coronary Heart Disease Before Age—					
	40	45	50	55	60	65
35	3	10	27	67	130	200
40		7	24	65	129	200
45			18	59	124	196
50				43	110	184
55					72	152
60						90

Coronary heart disease refers to the clinical manifestations of "coronary thrombosis," angina pectoris, etc., as defined.

Rates of first attack used in calculating the table are based on the Society's experience in 1949-50; rates of death are based on data for 1947-50. The table is constructed on the assumption that both these rates will continue indefinitely.

The "population" is as described in Table I, but excludes in each age group those who have already been attacked by coronary heart disease. Technical details may be found in Appendix 1.

be likely to get it in the next five years—that is, before they are 65. The cumulative "chances" up to age 65 are shown in the last column of Table III, and indicate, for example, that, of 1,000 at 35 or 40, 200, or one in five, are likely to get the clinical disease before age 65; and the proportion is little different at 45. Since the probability of getting the clinical disease under 35 years of age is extremely small, it may be said, roughly speaking, that the chances at 35 represent the chances from the beginning, and that they continue about the same till 45—that is, these medical practitioners under 45 years of age who have not so far been attacked by coronary heart disease have approximately a 20% chance of being attacked before they reach 65. The estimates for intermediate periods can easily be read from Table III—for example, of 1,000 at 50 years of age the chances are that 110 will get coronary heart disease before 60.

Table IV provides similar estimates for the chances of dying. It shows, for instance, reading again along the bold figures, that, of 1,000 men alive at 35, 75, or 7.5%, will be

TABLE IV.—Chance of Dying from Coronary Heart Disease

The number of male medical practitioners who would die of coronary heart disease before reaching certain ages.

Age x (Years)	Of 1,000 Men Aged x , the Number Indicated Below Would Die of Coronary Heart Disease Before Age—					
	40	45	50	55	60	65
35	3	6	12	23	42	75
40		3	9	20	39	73
45			6	17	37	71
50				11	31	66
55					20	56
60						38

Rates of mortality used in calculating the table are based on the Society's experience in 1947-50, and the table is constructed on the assumption that these rates will continue indefinitely.

The "population" is as described in Table I.

Technical details may be found in Appendix 1.

likely to die of coronary heart disease before they reach 65, should current death rates in the Society continue. Of 1,000 at 60, 38 may be expected so to die before 65.

Fig. 3 summarizes both tables in terms of a hypothetical 15 male practitioners aged 35.

Fig. 3.—The individual practitioner's chances. Of 15 practitioners aged 35, 12 can expect to be free of clinical coronary heart disease up to the age of 65, two to suffer from the disease without dying, and one to die of it before that age. These figures are based on the current experience of the members studied. They are less precise than the figures in Tables III and IV, from which they are derived.

Prevalence of Coronary Heart Disease

The probability among these medical practitioners of developing coronary heart disease before 60 years of age is about one in eight, before 65 about one in five; but that does not mean that 12 to 20% of them at 60-64 years of age will have the disease: many will die beforehand. It is worth trying to get some idea of the prevalence of coronary heart disease in these medical practitioners, of how many of them are affected during a particular time, whether by a first attack of the disease or any later manifestation of it. No corresponding figures seem to be available for any other population group. The following methods were used.

Consider, for simplicity, the population born, say, in 1890, who are alive at some time during 1950. This population could be divided as follows:

(a) Men who have an attack starting in 1950 which is the first clinical manifestation of coronary heart disease.

(b) Men who have an attack starting in 1950 which is a second or later clinical episode of coronary heart disease, but who do not have a first attack in 1950.

(c) Men who had an attack before the beginning of 1950, who continue to be incapacitated for part or all of that year, but have no attack starting in 1950.

(d) Men who have had an attack of coronary heart disease in an earlier year but, having returned to work, do not have an attack starting in 1950.

(e) Men who have never been attacked by the clinical disease, and do not suffer from it during 1950.

(In the present paper, of course, "attack" means "absence" for at least seven days or death.) These classes are mutually exclusive and make up the total of these medical practitioners or, indeed, of any "population." Class *a*, it will be remembered, gives the incidence and has already been considered. Class *b* together with Class *a* gives what may be called a *total attack rate* of all persons attacked in a period. This is not a particularly interesting statistic and has not been considered in this report.† Classes *a*, *b*, and *c*

FIG. 4.—Active prevalence of coronary heart disease, 1950. Male medical practitioners aged 45-64 inclusive. The active prevalence figures refer to 1950 only (Table V); the total attack rates are averages for 1949 and 1950 (see text), and the incidence rates for 1947-50 (Table I).

together, in the present material, form the total number of men disabled from work during the year for as much as a week, or who die—a figure that may be called the "active prevalence" of the disease. Columns 2 and 3 of Table V describe this in the present population, in the year 1950.

TABLE V.—Prevalence of Coronary Heart Disease in Medical Practitioners, 1950. Men Aged 35-64 Inclusive. Average Annual Rates per Thousand

Ages Last Birthday (Years) (1)	"Active Prevalence"		"Latent" Disease		"Total Prevalence" per 1,000 (6)
	No. (2)	Rate (3)	No. (4)	Rate (5)	
35-39	2	—	—	—	—
40-44	2	—	5	3.7	5.2
45-49	13	8.3	13	8.3	16.7
50-54	14	11.9	20	17.0	28.9
55-59	21	28.7	19	26.0	54.7
60-64	19	41.6	22	48.1	89.7
35-64 incl.	71	11.1	79	12.4	23.5
40-59	50	10.6*	57	12.4*	23.5*
40-64	69	15.2*	79	17.6*	33.2*

* Standardized rates.

"Active prevalence" = men disabled from work for at least seven days because of coronary heart disease, during any part of 1950. (The sum of Classes *a*, *b*, and *c* in the text.)

"Latent" disease = men who had an attack of coronary heart disease during 1940-9 inclusive, but who were not disabled from work for at least seven days on that account during 1950. (Class *d* in the text.)

"Total prevalence" = the sum of "active prevalence" and "latent" disease.

The mean of the counts of the relevant part of the Society's membership as on January 1, 1950, and January 1, 1951, was used for the population.

† The relevant rates per 1,000 in 1949-50 were: at 35-39 years, 0.9; at 40-44, 1.1; at 45-49, 5.1; at 50-54, 11.8; at 55-59, 18.1; and at 60-64 years, 23.7 (see Fig. 4).

The "active prevalence" rate climbs with age to about 40 per 1,000, or 4% of all alive at 60-64 years (Fig. 4).

This "active prevalence" rate, however, tells only part of the story, as can be seen from Fig. 1, where the total coronary mortality (column 7 of Table II) is plotted against the incidence of new cases (column 4 of Table I). It is at once obvious that there must be a steady and substantial build up of non-fatal cases which is seriously understated in the "active prevalence." In clinical terms it is clear why this rate is an inadequate picture of the total burden of the disease. The "active prevalence" measures the disability to work; but many who have an attack of "coronary thrombosis" return to work (it may be very modified work), and thus may not appear in a complete disability rate in any particular year, however much their mode of life is otherwise changed by the disease. These are the Class *d* cases, and quite a number of them may in fact have manageable angina of effort. What is required, therefore, is a measure of all who have been attacked by coronary heart disease, have survived it, and in whom the disease is "latent," though potentially it can become very "active" at any time and lead to complete disability to work—Class *d*.

The records were therefore searched for all men born in 1885-1914 (corresponding to ages 35-64 years in 1950) who had suffered from coronary heart disease in the period 1940-9 and who were alive in 1950, but not absent from work in that year on account of it, and thus included in the "active prevalence." The present material is particularly suitable for this kind of study because men can be observed till they reach 60 or 65: they cannot be written off the books for ill-health (as in a factory), nor do they lapse from follow-up study (as may happen in a cardiac clinic), and it is rare for any man to give up all his non-cancellable sickness policies.

The result of this search was to add to the "active prevalence" (column 3 of Table V) a "latent" prevalence of less active disease, (column 5) slightly larger than the "active prevalence" itself, and reaching almost 50 per 1,000, or 5%, at 60-64. These figures, moreover, may slightly underestimate the true position, as the experience before 1940 was not examined, and this might have yielded a few further survivors to add to the totals with "latent" disease in 1950.

The "active prevalence" and "latent" disease can be added together to give an estimate of the total clinical prevalence, or the cumulative burden of the disease, in this population group (Fig. 5). The "total prevalence" of coronary heart disease in these medical practitioners in 1950, at 50-54 years of age, was about 3% in all. In those

FIG. 5.—Total prevalence of coronary heart disease, 1950. Male medical practitioners aged 45-64, inclusive (see Table V). Latent disease = men attacked in a previous year who are not absent on account of the disease during the year.

surviving to 60-64 years of age the "total prevalence" was about 9%. In the light of such figures terms like "epidemic" may be justified.

Prognosis

Up to this the main problem has been, What proportion of men are attacked by coronary heart disease?—for example, as in Tables I, III, and V. Attention will now be turned to prognosis, and the questions that will be asked can be expressed as, What happens to men so attacked? The present series of questions, that is, deals only with the cases of the disease, and not with the population in which these occur; the approach will be the usual one of the clinician, not that of the epidemiologist. It is therefore possible to make use of cases occurring in the Society before 1947, even though details of the membership at different ages in those years are not available in a form suitable for calculation of rates. The records of first attacks of coronary heart disease

TABLE VI.—*Prognosis for Life and Death in "Coronary Thrombosis." Experience of Medical Practitioners from the Onset of the First Clinical Attack, 1940-51. Men Aged 40-64 Inclusive*

(A) Percentage of men dying and surviving at various periods from onset of first attack.

Time	First 6 Days	Rest of 1st Month	Rest of 1st Year	2nd and 3rd Years	4th and 5th Years	6th and 7th Years
Dying in period	30	8	2	6	3	3
Cumulative mortality*	30	38	40	46	49	52
Surviving period	70	62	60	54	51	48

* Up to end of period specified.

(B) Percentage of men dying and surviving, by age.

Ages Last Birthday (Years)	Dying in First 6 Days	Dying in 1st Month	Dying in First 3 Years	Surviving First 3 Years
40-49	29	33	39	61
50-64	31	40	50	50
40-64 incl. ..	30	38	46	54

These tables are based on the experience of 192 medical practitioners, who had a first attack of "coronary thrombosis" between January 1, 1940, and December 31, 1950. Observation was continued till June 30, 1951, except for men who died or whose policies terminated before. The total number followed in the fifth year was 46, and in the seventh, 26. In the third year there were 35 men aged 40-49, and 39 aged 50-64 inclusive. Men whose first presentation of coronary heart disease was not as an attack of "coronary thrombosis" were excluded from these tables. Details of the methods of calculation used may be found in Appendix 2.

TABLE VII.—*Absence from Work on Account of Coronary Heart Disease After the First Attack of "Coronary Thrombosis." Experience of Medical Practitioners who Survived Their First Illness, 1940-51. Men Aged 40-64, Inclusive*

(A) Second Absences		(B) Working Time Lost	
No. of Years After the End of First Attack = t	% Survivors of First Attack Absent from Work Again, Because of Coronary Heart Disease, Within t Years	No. of Year After the End of the First Attack	Average Time Lost per Man Because of Coronary Heart Disease During the Year
(1)	(2)	(3)	(4)
1	14%	1st	0.6 month
2	30%	2nd	1.1 months
3	33%	3rd	0.9 month
4	35%	4th	0.8 "
5	45%	5th	0.8 "
6	49%	6th	0.9 "

The first absence for "coronary thrombosis" was taken to represent the first attack.

Columns 1 and 3: The date of return to work was taken as the "end of the first attack."

Column 4: "Time lost" is calculated from the number of days of total disability to work. No attempt is made to estimate the number of working hours lost, by distinguishing working days from Sundays and public holidays; and no allowance could be made for periods of absence lasting less than a week, or for periods of part-time work.

There were 107 survivors of the first attack. For Table A observation was continued until June 30, 1951, or until the second absence (or death without further absence), except for men whose policies terminated. The number under observation in each year diminishes from the original 107 to 35 in the fourth year and 21 in the sixth year. For Table B the only difference was that observation did not cease with a second absence. The numbers under observation in any year are therefore slightly greater.

Details of the methods used in calculating the proportions and averages in these tables are given in Appendix 2.

in 1940-6 were therefore extracted, and the information was added to that already available for 1947-50. (Medical papers relating to most of the deaths before the war were lost by enemy action in 1940.) The Society's experience is a useful basis for studies of prognosis because, as stated, regular contact is kept with all members until they reach the age limit or die. On the other hand, the fact that the data deal only with men under 65 years of age is a serious limitation in discussing the prognosis for life, though not of course for work. The present inquiry was stopped on June 30, 1951, an arbitrary date on which it was convenient to cease observation of the men. Appendix 2 describes the methods adopted in drawing up Tables VI and VII.

Prognosis in "Coronary Thrombosis"

Without arguing the unitary pathology and, in particular, functional pathology of coronary heart disease associated with atheroma, this discussion falls naturally into two parts—the prognosis in "coronary thrombosis" (myocardial or cardiac infarction), and that in angina pectoris (angina of effort). The level of diagnosis in a group like this is probably high enough to justify the division. The prognosis in "coronary thrombosis" will be dealt with first.

Prognosis for Life and Death

It is already clear from Table II that the crucial period for life and death, at any rate in the ages being considered, is the first few days of the first clinical attack.

First Days of First Clinical Attack.—In the 11 years 1940-50 inclusive there were 192 first diagnoses of "coronary thrombosis," as defined, in men aged 40-64 who held the relevant insurance. These men may be regarded as a cohort to be followed through. The proportion who died in the first six days of the first clinical attack (Fig. 6) was 30% (Table VI.A). It varied a little with age—from 28% at 40-44 years, to 34% at 55-59 years—and the relative stability of this fraction through middle age was not altogether expected. There was no change in the fraction from 1940-6 to 1947-8; in 1949-50 it was rather lower, which may be an indication, possibly, of an increasing diagnosis of less classical and milder cases.

Rest of the First Month.—The next column in Table VI.A shows the mortality in the remainder of the first month. It is still heavy—8% of the original number of men (and 11% of those surviving)—but not nearly so heavy as in the first few days (Fig. 6). In total, therefore, about 38% of these medical practitioners who were first attacked by coronary heart disease in the form of a "coronary thrombosis" in 1940-50 died in the first month of their illness; about 62% survived the first month. It is not known whether any of these men received anticoagulant treatment. It is unlikely that the deaths in the first few days could have been much affected by this form of therapy, and the number of deaths in the remainder of the first month, both in 1940-6 (when there must have been little such treatment) and in 1947-50 (when there may have been much), is impossibly small for

FIG. 6.—Prognosis for life and death in "coronary thrombosis." Experience of medical practitioners from the onset of the first clinical attack, 1940-51. Men aged 40-64 inclusive (see Table VI.A).

any comparisons; all the more since other changes in the same period, such as an improvement in diagnosis, need to be considered.

Attention is now turned to the survivors of the first month, whose passage, it may be said at once, is decidedly less stormy than heretofore.

In Following Years.—In the remaining 11 months of the first year another 2% of the original cohort died from coronary heart disease, or its complications, and this figure is typical of the annual experience in the next six years. Table VI.A gives some detail—in the second and third years from the onset, for example, a further 6% died, making a total mortality up to the end of the three years of 46% (30%+8%+2%+6%); 54% of the original cohort who could be followed survived the three years.

In Younger and Older Men.—Table VI.B. gives a simple analysis by age. There is little difference in the outlook during the first six days; thereafter, for the three years which can be adequately followed, the prognosis seems to be better in the younger men. By the end of the third year there is a difference of 11%, with 61% of the men aged 40-49 at onset of first attack of "coronary thrombosis" surviving, but 50% of those who were aged 50-64 years. This conforms with the general experience on the deterioration of prognosis with age (Friedberg, 1949; Eckerström, 1951). However, the numbers are too small to exclude the possibility that we may be dealing with a chance effect.*

Prognosis for Further Sick Absence

Analysis of the further absences from work on account of coronary heart disease among those who have survived their first illness is worth while in clinical and social terms, if not in pathological terms. The frequency of such further absences is high in the two years following the return to work, Table VII.A, with 30% of the men having a second bout of absence. The cumulative proportion of those who have had a further sick absence for coronary heart disease, or its complications, reaches about 50% by the end of the sixth year. No differences with age were discernible in these further absences—that is, the younger men seemed to have as many second absences as the older, though, as was noted before, their mortality on the whole may be less. Numbers, however, are small in the different age groups.

Prognosis for Work

The point of view here is rather different: in the formulation of any policy for, say, the future employment of men

**Prognosis in the First Attack and Second Attack.*—Clinically it is even more important to know the outlook in the various attacks of "coronary thrombosis." The present material, however, is not very suitable for this type of analysis. These records are only of sick absence and death, and a further attack supervening during the convalescence from a first, for example, would not necessarily be recorded separately, if the patient had not yet returned to work from the first illness. Nevertheless, figures for the first month do probably refer to the first attack of "coronary thrombosis," and probably include most of the deaths in the first attack. The only indication that can be given of the mortality in second attacks is the experience in second absences. Many of these very likely refer to second attacks; but a few may refer to even later attacks (if more than one attack was included in the first absence); and a few may be due to relapses of the first attack; or complications and cardiac failure; or to external factors aggravating the cardiac condition. Following are the relevant figures; they show the trend with age, particularly after the first week:

Ages Last Birthday (Years)	Experience	First Attack/Absence.		Second Absence (and ? Attack)
		First 6 Days	Rest of 1st Month	
40-49 incl.	No. of men followed through . . .	63	45	16
	No. dying . . .	18	3	2
50-64 incl.	No. of men followed through . . .	129	89	17
	No. dying . . .	40	12	6

Third absences are too few for analysis.

with coronary heart disease it is necessary to know their capacities as well as their needs. In practical terms, how much time may men who have survived their first attack (as reckoned by their return to work after the first illness) expect to lose in the years thereafter? The present material contains some evidence on this, and its restriction to ages under 65 does not matter so much. The length of each absence is known, and it is therefore possible to calculate the average amount of time lost by each man per year. It is of course likely that some of the men who did not claim sickness benefit were in fact partially disabled and on less than full duty; but this partial disablement cannot be included in Table VII.B. The figures in that table indicate that, on average, the survivors of the first clinical attack of "coronary thrombosis" missed only about one month's work in each of the next six years because of coronary heart disease (Fig. 7). Some of these men, as shown above, died during the years following the first attack; they are included in the present account until the year in which they went absent because of their final illness. More precisely, therefore, Table VII.B indicates, for instance, that the men who survived to the beginning of the fifth year from the end of the first attack lost an average of 0.8 month (or about four weeks) in the fifth year because of coronary heart disease.

FIG. 7.—Prognosis for work. Experience of medical practitioners who survived their first illness, 1940-51. Men aged 40-64 inclusive. Sick absence for other than coronary heart disease, its complications and consequences, has been ignored (see Table VII.B).

Prognosis in Angina Pectoris

There were 42 first attacks of angina pectoris (or "of effort") during 1940-50 which were ascribed to coronary atheroma—or in which no underlying pathology was stated—in comparison with the 192 first attacks of "coronary thrombosis"; (and nine, which have been ignored, of "coronary insufficiency" and the like). Presentation with angina pectoris became commoner with age (Fig. 10). The first absence in these cases of angina lasted on average for about three months compared with about five months for "coronary thrombosis." Later absences of men who initially were absent with angina were increasingly ascribed to "coronary thrombosis," of course, and lasted longer.

With such small numbers examination of prognosis is less profitable, but one fact did emerge clearly: the outlook for life among the cases first presenting as angina pectoris is

FIG. 8.—Prognosis for life and death in "coronary thrombosis" and angina pectoris, 1940-51. Male medical practitioners aged 40-64, inclusive.

very different from that of the men first presenting as "coronary thrombosis." In angina it is similar, in the five years that can be studied, to the prognosis in men who have survived their first critical month of "coronary thrombosis" (Fig. 8). About 11% of the men first presenting with angina pectoris died in the next five years. About 16% of those who survived the first month of "coronary thrombosis" died in the next five years, but this figure has to be added to the 38% who had already died in the first month. In terms of a "severity" spectrum of the natural history of coronary heart disease, therefore, the more slowly developing, relatively benign, cases of angina pectoris seem to be at one end, the "sudden" deaths from "coronary thrombosis" as first clinical manifestation, at the other, with a wide range of severity between.

Summing-up of Prognosis in Middle Age

If the figures in this series are at all representative, "coronary thrombosis," as regards its mortality, belongs to the most "acute" diseases rather than to the "chronic" diseases. It is clearly unwise to consider the prognosis for life of men first presenting with "coronary thrombosis" except in terms of the first days of the first attack (30% mortality in six days, in this series), the rest of the first month (8% mortality), and the years thereafter (about 2% of the original cohort died annually in each of the next seven years) (Fig. 9). About 80% of those who survived the first month were

Fig. 9.—Prognosis for life and death in "coronary thrombosis." Experience of medical practitioners from the onset of the first clinical attack, 1940-51. Men aged 40-64 inclusive. Distribution of deaths by time from onset of first attack (see Table VI, A).

Number of Deaths in Each Week in the First Year			
Week	Deaths	Week	Deaths
1	58	7	1
2	7	8-10	0
3	5	11	1
4	2	12-18	0
5	2	19	1
6	0	20-52	0

alive at the end of five years. This improvement after the first month was due not so much to mortality in later attacks being less than in the first—though this also may be so—as to the fact that a second attack does not necessarily occur at all for some years. On the present evidence, about half the men who survived their first illness and returned to work did not have as much as a week's further sick absence for coronary heart disease in the six years following. In consequence the work record, for whole-time or part-time work, of men who survived their first attack is good: they may each lose on average only about four weeks a year for coronary heart disease in the six following years. The prognosis for life of men first presenting as angina pectoris seems to be better than that of men first presenting as "coronary thrombosis." Indeed, they seem to miss the early crises altogether, and their outlook, for a few years at any

rate, is similar to that of the men with "coronary thrombosis" who have survived the first terrible month.*

This discussion of prognosis deals only, of course, with middle-aged medical practitioners. The evolution of coronary heart disease in the elderly may be quite different.

Mode of Presentation of Coronary Heart Disease

Fig. 10 illustrates the fraction at each age that the cases of "sudden" death form of all presenting coronary heart disease in these medical practitioners. It can now be stated

42 cases Presenting as Angina Pectoris 17%
143 cases Presenting as "Coronary Thrombosis" (including 9 cases of Coronary Insufficiency, etc.) and surviving the first 6 days 59%
58 cases Presenting as "Coronary Thrombosis" and dying within 6 days 24%

Fig. 10.—Mode of presentation of coronary heart disease, 1940-50. Male medical practitioners aged 40-64, inclusive.

in round numbers that at 40-44 years of age coronary heart disease presents as "sudden" death (within six days) in about a quarter of the cases, as less severe "coronary thrombosis" in about 60%, and as angina pectoris in somewhat over 10%. At 60-64 years of age the fractions are again about a quarter as "sudden" deaths, somewhat over 50% as not so severe "coronary thrombosis," and somewhat over 20% as angina pectoris. These three manifestations

*It is perhaps worth while to stress here the difference between two fractions which are discussed in this paper. The first, mentioned previously under "Mortality Rates," gives the proportion of deaths within six days of the onset of the first attack—that is, "sudden" deaths—formed of all deaths from coronary heart disease (whenever these deaths occurred, whether in the first or later attacks). At ages 40-64, in the 11-year period 1940-50, this fraction was 56%. The second fraction, discussed in the present section on prognosis, is the proportion of "sudden" deaths among all the first attacks of "coronary thrombosis." In the same period, and in men of the same age, this second fraction was 30%. Since it is probably true that most people who have coronary heart disease, especially "coronary thrombosis," will eventually die of it, there is at first sight an apparent contradiction here. Closer examination shows, however, that the first fraction—that is, of the observed deaths—depends on the ages studied; whereas the second—that is, of first attacks—does not appear to vary much, at least within the age range 40-64. During 1940-50 "sudden" deaths, as said, formed 56% of all "coronary" deaths: but this 56% was made up of 62% at ages 40-49, 58% at 50-59, and 44% at 60-64 years. It is easy to account for this variation. At early ages there will be few people who have been previously attacked by the disease and who are therefore likely to die at long intervals after the first attack. The fraction, therefore, falls with age, and quite possibly at greater ages than 65 it will be even lower than 44%. The fraction which "sudden" deaths form of all coronary deaths at all ages is thus likely to be considerably lower than 56%, and the contradiction between this figure and that of 30% may well be a result of the particular age range studied, and the limited period under observation. However that may be, the first and higher fraction of 56%, applying as it does to men aged 40-64, brings into prominence the fact that more than half of the deaths that do occur in middle age, when the problems of the disease are at their most serious, are in fact "sudden."

accounted for all but nine of the 243 "first presentations" of coronary heart disease in the years 1940-50, inclusive. The nine were variously described as "coronary insufficiency," etc.

PART II: THE DISEASE IN GENERAL PRACTITIONERS AND IN OTHER DOCTORS

In a social medical inquiry, concerned eventually with possible relationships between health and ways of living, "medical practice" is rather a wide social category to be assumed homogeneous in its experience of a disease. The general practitioner, the consultant, and the medical officer of health may lead professional lives at least as disparate as many "occupations" usually distinguished in this type of study. The practical difficulty is how, without personal inquiry, to decide which of a large group of doctors are G.P.s, consultants, etc., so that the experience of different sections of the profession can be compared. The only readily available source of information on what doctors do is the *Medical Directory*; and study of its contents showed that it is practicable to classify doctors into the following broad categories:

Category 1.—This comprises those who, it may reasonably be presumed, are full-time general practitioners (or almost so)—doctors with no appointments and merely a name and address in the *Directory*; or with certain types of appointment, such as Post Office medical officer or appointed factory doctor, and no other appointments.

Category 2.—This, so far as can be determined, is composed of full-time clinical consultants/specialists—men on the staff of teaching hospitals, or certain other major hospitals; and men with at least two specialist appointments at non-teaching hospitals (in certain cases having particular diplomas). Any indications of general practice, such as the mention of a partnership, would exclude a man from this category.

Category 3.—An intermediate group, fairly well defined outside the university centres, of general-practitioner specialists—that is, men who are both; who are in general practice and also do some specialist work, usually having one appointment, such as surgeon or physician (but not "clinical assistant" or "medical officer") at the local non-teaching hospital; doctors recorded as being merely "on the staff" of cottage hospitals are not included. Men in this category will be referred to as *G.P.-Specialists* in contrast to full-time general practitioners (Category 1), and full-time consultants/specialists (Category 2).

Category 4.—A number of small groups of various full-time public officials—medical officers of health, doctors in Government departments, regular officers in the armed Forces; and to these may be added a small number of full-time staff of mental and fever hospitals and tuberculosis sanatoria who are not of consultant status; and men holding academic non-clinical posts.

Category 5.—Retired practitioners; those of "address unknown"; and those who could not be classified.

This seemed a useful grouping, and it was decided to apply it in the next stage of the inquiry—an attempt to find whether any of the major sections of the profession, as these were represented in the Society, had more or less coronary heart disease than any other. There is good reason to believe that there is a high level of diagnosis among all the members, and that in a condition of such duration and gravity extraneous factors that might affect the sick-absence rates for minor ill-health will not apply. The attempt necessarily involved three steps: (1) to determine the total number in the various categories among the relevant members of the Society, at different ages, by sampling; (2) to identify the occupational category in each recorded case of coronary heart disease; and (3) to calculate the incidence of the disease in the various categories. It was decided to make a pilot test of the experience of 1949 and 1950.

Ten per cent. of the relevant membership at each year of age over 45 was taken (a strictly random sample using random sampling numbers); and the "first attacks" of 1949-50 in members aged 45-64 were shuffled in with this sample. First attacks only were included because men may change their jobs on account of their health, and if the

possible effects of work on disease are the object of study, not the possible effects of disease on the work that men do, first attacks are likely to give the most reliable information. The cases were included with the sample to preserve the ignorance of the unit's staff of individual identity, and thus to eliminate any possible bias, as well as to preserve the confidential nature of medical records. All these persons—the 10% sample plus those attacked for the first time—were then marked in the *Medical Directory*. The two authors of this report who were ignorant which of the names represented a man with a first attack and which did not independently categorized all the names, discussing together and agreeing on the doubtful ones; there was no particular difficulty in allocation, and the great majority sorted themselves at once. The third author, who held the key to the names, then placed each person appropriately, by age and category, as a "first attack" or as a member of the sample population (as a matter of fact four "first attacks" were also drawn in the sample). Finally, rates of incidence of coronary heart disease were calculated for the various categories, on the assumption that the occupations in the whole of the relevant membership were distributed in the same way as those in the sample. The results, which were surprising, are summarized in Table VIII, for the general-practitioner group and the rest.

TABLE VIII

Findings	Category	
	1 General Practitioners	2+3+4+5 The Rest
No. of first attacks of coronary heart disease in 1949-50 at 45-64 years	46	21
No. in 10% sample of "population"	213	197
Annual incidence per 1,000 at 45-64 years (standardized for age)	11.8	6.2
Standard error of this rate	±2.1	±1.5

Since it is unlikely that there is much difference in the level of diagnosis among different sections of the profession, or in the extent to which they would claim benefits in such serious and prolonged illness, these figures were suggestive of a true excess among the general practitioners. Critical examination of the data failed to upset this trend, which was evident in all five-year age groups, in each of the major geographical regions of the United Kingdom, and when the general practitioners were compared with each of the other categories taken by itself—all evidence of that "internal consistency" of the material so important in dealing with small numbers. Various manipulations had no effect—for example, the reallocation of "marginal" occupations among the various categories, the exclusion of all who were classified as general practitioners on negative grounds (that is, because they had no more than their names and addresses in the *Directory*), and the separation of fatal from non-fatal attacks. It did appear that the members designated as full-time general practitioners had a higher incidence than the other members of the Society.*

There are three major possible sources of weakness in the above trial: (1) the limitations of sampling; (2) the difficulties, and possibly the "fluke" effect of the small number of attacks, whereby one or two might materially alter the rates; and (3) the allotment of occupation on the basis of the *Medical Directory*. These weaknesses had to be dealt with so far as possible, and this is what we did. The first problem was met by drawing a further, and quite separate, 10% sample of the relevant membership; the occupational

*It may be mentioned that there was no material difference in the ages at which the general-practitioner members and the men in the other categories took out their first immediate benefit policies with the Society. The average age of this among the "cases" of coronary heart disease was 34.6 years in the general practitioners and 32.6 in the remainder; among the "sample" it was 32.6 years in the general practitioners and 31.4 in the others.

distribution of this sample was very similar to that of the first. The number of cases of coronary heart disease was increased by including the first attacks of 1947-8. (A further "trial" was then carried out by shuffling these 1947-8 cases in with the *new* sample, and the results were similar to those tabulated above.) The third problem, the allotment to type of work, was more troublesome. It was decided to ignore Category 5—the "retired," etc.—which left the following categories of membership:

Category 1 (the full-time) General Practitioners
Categories 2, 3, and 4 the Other Doctors

All in these four categories who were resident outside the United Kingdom were also excluded. The number of cases in 1947-50 was thus reduced by five, and the size of the sample by about 4%. The small changes in the occupational distribution of the membership from January 1, 1947, to January 1, 1951, were assessed, and the sample of the total relevant membership finally set up was an average for the whole four-year period 1947-50. On the main issue, however, it was clear that some quite independent check of the occupational allotment was necessary. We therefore decided to classify sufficient of the two samples and sets of cases again, and on this occasion from the official National Health Service lists. Only such a procedure, it was felt, would adequately test the categorization already made from the *Medical Directory*. It can be said straight away that the result of this check showed a surprising degree of conformity between the findings from the National Health Service lists in mid-1951 and the allocations already made from the *Directory*; surprising in view of the changes introduced by the N.H.S., the fact that a certain proportion of doctors did not join it, and because a number of men must have retired or died between the date of the *Medical Directory* used for categorization and that of the lists used for checking (see Appendix 3).

The final analysis can now proceed with some confidence. The two 10% samples were pooled, giving a one-in-five sample; as were also the first attacks of 1947-50. In addition, further to increase the numbers, the first attacks at ages 40-44 in the years 1947-50 were now included, and a one-in-five sample of the relevant membership in that age group also was drawn and categorized, making now a grand total of just over 1,100 names. Tables IX, X, and XI assemble the results by age and category, so far as is reasonable with the small numbers involved. Table IX sets out the

See notes to Table IX.

Rates per 1,000 were calculated from the number of first attacks (numerator), and the total numbers corresponding by age and occupation in the Society (denominator). These total numbers were estimated from the sum of two independent 10% samples drawn by single years of age from the relevant membership. No rates are calculated for less than three cases.

See notes to Tables IX and X.

Average membership estimated from the 20% sample.

The standard errors of the rates quoted above allow for the standardization.

Standardized rates are based on the civilian population of England and Wales in mid-1949. (The standardized rates at 45-64 inclusive were Category 1, 10.8 per 1,000; and Categories 2+3+4, 5.5 per 1,000.)

main findings, Table X gives the details, Table XI is a summary table.

Three things stand out:

(1) In this Society, during 1947-50, the full-time general-practitioner members aged 40-64 had about twice as high an incidence of coronary heart disease as the other members (Table IX). The inclusive figures of 8.8 and 4.4 per 1,000 are standardized to take into account the differences of age composition in these two large groups. If Categories 1 and 3, the only ones in which general practitioners are at all likely to be classified, are merged and compared with the remainder (columns 6 and 7 of Tables X and XI), the incidence for this all-inclusive general-practitioner group is still about 1.8 times that of the others.

(2) The excess among general-practitioner members is seen at all ages studied, but is greater at 40-49 years than at 50-64 (Table IX, and columns 1 and 5 of Table X), the ratio of the incidence being:

	General Practitioners : (Category 1)	Other Doctors (Categories 2+3+4)
At 40-49 years	3.3 : 1	
" 50-59 "	1.8 : 1	
" 60-64 "	1.7 : 1	

(3) There is, unexpectedly, no indication of an occupational gradient with the intermediate group of "G.P.-Specialists" between the general practitioners and the specialists. Table XI shows that the standardized incidence at 40-59 and 40-64 years of age among general practitioners is different from the rest—the specialists, G.P.-specialists, and public officials; and the composite rate for these three categories as shown in column 5 of Table XI is a fair account of them all (Fig. 11). The numbers, however, in Categories 2, 3, and 4 are very small, so that no conclusions can be drawn about them individually.*

FIG. 11.—Incidence of coronary heart disease in general practitioners and other doctors, 1947-50. Men aged 40-64, inclusive. Category 1, general practitioners; Category 2, consultants/specialists; Category 3, G.P.-specialists; Category 4, public officials. (See Tables IX, X, and XI for further details of membership of Society, etc.)

*Statistical "significance" of the differences in the rates.—The main difference—that is, that between the rate for Category 1 and the combined rate for Categories 2, 3, and 4, at ages 40-64 inclusive—might appear by chance, if in fact there is no occupational difference; less than once in 1,000 times. The significance of the differences between the rate for Category 1 and the rates for Categories 2, 3, and 4, taken separately, is also indicated below:

Ages	Category 1 and			
	Category 2	Category 3	Category 4	Categories 2+3+4
p at 40-59 incl. $\approx$	0.002	0.003	0.04	0.001
p „ 40-64 „ $\approx$	0.003	0.003	0.02	0.0007

The differences among Categories 2, 3, and 4 are not significant by any standard.

p for the difference between Categories 1+3 and Categories 2+4 is 0.004 both for ages 40-64 and ages 40-59; for the difference between Categories 1+3 and Category 2 alone it is 0.009 for ages 40-64, and 0.006 for ages 40-59.

These values of p allow for the facts that the population was estimated from a sample, and that for each comparison the sign of the difference is consistent in each age group. Consequently, these values of p cannot be deduced directly from the standard errors of the standardized rates quoted in Table XI.

The cases are too few to quote many special rates that would be of interest. But it can be said that the findings were rather stable, and the general-practitioner members did have an excess in each of the four years 1947-50; in fatal as well as in non-fatal cases; in angina pectoris as well as in "coronary thrombosis," in diagnoses with and without "specialist confirmation"; and in the different parts of the United Kingdom taken separately. Recalculation of Tables III-VII in terms of general practitioners and other doctors has not yet been undertaken.

New or Old?

Clearly the next question is, When did this higher incidence of coronary heart disease among the general-practitioner members appear; is it a new or an old phenomenon? Adequate records of the Society for dead members are available only as far back as 1940, and the question therefore becomes, Is the higher incidence among these general practitioners a post-war development, or was the experience of 1940-6 similar to that of 1947-50? Unfortunately, though there are some interesting pointers, it is not possible to answer even this question at all satisfactorily.

To obtain such an answer two sets of facts would be needed about the experience of 1940-6, just as they were needed for 1947-50: (1) the number of first attacks at different ages in each occupational category during 1940-6; and (2) the number of members at different ages in each category during those years. The first attacks of 1940-6 are already known from the study of prognosis, and these can be categorized from the *Medical Directory* of the year preceding the attack. But for various reasons it is quite impracticable to reconstruct the age and occupational structure of the Society in the war years, so that rates comparable with those of Tables IX, X, and XI may be calculated. An idea of the main characteristics of the wartime membership can be obtained, however, if two assumptions may be made: (a) if it can be assumed that the occupational distribution of the Society's members in the years 1942-5 was similar to that found five years later in 1947-50, in men five years older—that is, if it can be assumed that the proportion of general practitioners to other doctors, aged 40-59, in 1942-5 was similar to the proportion observed in the members aged 45-64 in 1947-50; and (b) if it can be assumed, further, that the occupational distribution of the members in 1942-5 was reasonably typical of the longer period 1940-6. In defence of these assumptions it may be stated that the membership of the Society is a very stable one, especially over 40 years of age, and it remained particularly stable during the war; the ratio of general practitioners to other doctors, moreover, was found to be similar in each five-year age group during the years 1947-50 except in the oldest age group.

The assumptions are therefore fairly reasonable: nevertheless, with such hypothetical information about the "population," all that can be expected are estimates, rather than facts, about what took place during the war.

In Table XII the 1940-6 material is analysed, so far as the nature of the information permits. The occupational distribution of the members in 1940-6 is estimated, as described, by projection backwards; the average number of first attacks of coronary heart disease, per year, in men aged 40-59, is given; and the annual averages of cancer deaths at the same ages have been added for comparison. The ratios between these average annual numbers are given in parentheses and in italics.

TABLE XII.—Findings in Men Aged 40-59 Years

	1940-6		1947-50	
	General Practitioners	Other Doctors	General Practitioners	Other Doctors
Occupational distribution of membership (Ratio)	1.2 : 1		1.3 : 1	
Average no. of first attacks of coronary heart disease per year	6.9	6.3	17	5.8
(Ratio of averages)	(1.1 : 1)		(2.9 : 1)	
Average annual number of first attacks of coronary heart disease fatal in the first month	1.9	2.0	5.3	1.5
(Ratio of averages)	(0.9 : 1)		(3.5 : 1)	
Average no. of deaths from malignant disease per year	1.6	1.7	2	2.3
(Ratio of averages)	(0.9 : 1)		(0.9 : 1)	

N.B.—There are no rates in this table, but merely numbers of cases per year in two groups, and ratios of these numbers to each other.

There are several points of interest in this table. The ratio of the first attacks of coronary heart disease (general practitioners: other doctors) is different in 1940-6 from that in 1947-50 (1.1:1 and 0.9:1, in 1940-6, as against 2.9:1 and 3.5:1 in 1947-50). The ratios in 1940-6, when compared with the ratio of the numbers in the two occupational groups in those years (1.2:1), suggest that there was little, if any, excess coronary heart disease among general practitioners during the war.† If the experience of the "G.P.-Specialists" is added to that of the general practitioners the findings are again unaffected. These figures are interesting in light of the American observation that there was no material difference in the coronary mortality rates of medical specialists and non-specialists in the years 1938-42 (Dublin and Spiegelman, 1948).

Table XII also suggests that the excessive number of first attacks of coronary heart disease among the general-practitioner members in 1947-50 was due more to an increase of first attacks in them than to a reduction in the "other doctors." The relevant figures, as given in the table, are 6.9 and 17 (per annum) for general practitioners, compared with averages of 6.3 and 5.8 for the other doctors. The occupational changes in the membership during 1947-50 are known to be very small, and there is nothing in this, or in the increase even of the total number of members with non-cancellable insurance between 1940-6 and 1947-50, or in the ageing of the members within the range 40-59 years, that could possibly account for this more than doubling of the number of first attacks of coronary heart disease among the general practitioners.

Furthermore, Table XII suggests that this increase of first attacks among general practitioners in 1947-50 may represent a real increase, and is not merely the result of improving diagnosis with readier recognition of milder, or atypical cases. The average numbers of fatal and non-fatal first attacks among the general practitioners have increased in step. The proportion, therefore, of first attacks which were soon fatal—a proportion that may be used as a crude index of the severity of the cases being recognized—did not change materially in the two periods (1.9/6.9, 27%, almost equals 5.3/17, 31%).‡ The similarity of this fraction in 1940-6 and 1947-50 suggests that there was little change in the level of diagnosis in the two periods. The similarity of these early case-fatality ratios in the general practitioners and other doctors (in the other doctors the ratios in the two periods were 32% and 26%) supports, also, the proposition that the level of diagnosis in these two groups was similar.§

Finally, it may be remarked that the stability of the cancer mortality figures suggests that there has been no general breakdown in the Society's recording system, or any major "experimental error" affecting in particular one section of the membership. This stability, moreover, strengthens the previous impressions of the stability of the membership of the Society.

Such confirmatory arguments, however, cannot substitute for the absence of needed facts. An attempt had to be made to deal with the problem, and this is the best we have been able to do. It will be remembered (Fig. 12; Josiah Macy Jr. Foundation, 1951) that there is some evidence of a diminution of coronary heart disease during the recent war in several European countries, and of a rise after the war. Possibly there was some general factor that operated to produce an "abnormal" occupational distribution among the membership during the war. At the most it may here be said that there seems to have been little, if any, excess of coronary heart disease among general-practitioner members during the war. It appears that there may have been some increase of the disease among these general practitioners

†The same indication arises if the men first attacked by coronary heart disease in 1940-6, who had a second absence for this in 1947-50, are categorized. There were 26 such men, aged 40-59, in the four years 1947-50—13 general practitioners and 13 other doctors; that is, an average of 3.3 per year in both groups, and a ratio of 1.0:1. These further absences, it should be noticed, occurred in exactly the same population, and in the same period, that showed occupational group averages of 17 and 5.8 for first attacks, with a ratio of 2.9:1 (see Table XII).

‡There were, in fact, as already mentioned, some signs of an improvement in this early case-fatality ratio during 1949-50, but this is too slight to affect the argument, the more particularly as better treatment may have contributed to the reduction in fatality.

§Another indication of the level of diagnosis is the number of such less definite diagnoses as "myocardial degeneration," "myocarditis," etc., compared with the definite diagnoses alone accepted as coronary heart disease for the purposes of this investigation. These less definite diagnoses were few in either period, or in either group. The average annual number of "first attacks" of "myocardial" disease in 1940-6 was 1.1 both for general practitioners and other doctors; while in 1947-50 the figures were 1.5 and 1.0, respectively.

FIG. 12.—Mortality from heart disease, 1931-49. Men aged 45-64, inclusive. England and Wales. (Registrar-General.) (a) $\times$ — $\times$ — $\times$ Diseases of Coronary Arteries, Angina Pectoris. (Int. List No. 94) (b) $\cdots$ — $\cdots$ — $\cdots$ Chronic Myocardial Disease, excluding those specified as Rheumatic, but including Myocardial Infarction. (Int. List Nos. 93 c, d; 162 a, c.) (c) — The sum of (a) and (b).

since the war, and this increase may be related to the excess of the disease found among them in 1947-50. Because of the hypothetical nature of the 1940-6 "population" it is impossible to say by how much the true average rate of first attack among the general practitioners increased from 1940-6 to 1947-50, whether one age group was affected more than another (though the indications are that men in their fifties were affected at least as much as men in their forties), or when the increase began. The higher incidence among these general practitioners, it may be recalled, was present throughout the four years 1947-50. There is unfortunately no other evidence to appeal to for confirmation—or otherwise, and it is a particular pity that analysis of the pre-war situation is impossible.

Part II, above, is an example of simple epidemiology (Gordon, 1950)—the exploration of rates of incidence in different social groups. This step may of itself make an immediate contribution to aetiology, but its main value is usually to raise questions rather than to answer them, and at the same time to provide an economical "way in" to further study, through comparison, for instance, of the circumstances of high and low incidence. In epidemiological inquiries large-scale hypotheses can often be formulated and tested, supplementary to those of the bedside and laboratory; and hypotheses framed in clinical and laboratory study can often be independently validated. Finally, as an experimental science, epidemiology can try to apply its notions "in the field"—for example, by correcting faults that appear to be relevant and observing the subsequent incidence.

If the situation in this Society is at all representative, interesting and important questions must arise about the health of doctors, and about the possible contribution which doctors might be able to make, through their own health and sickness, to the better understanding of coronary heart disease, and, eventually, to the development of a rational preventive programme. But is the experience of the Society true of the whole profession? We are quite unable to answer this question. A great deal of effort could be spent in an attempt to estimate how typical the members of the Society are of all the doctors in the country. For instance,

a superficial examination of the available statistics indicates that rather more than a quarter of all general practitioners aged 40-64 years appear to be members included in this inquiry, rather less than a quarter of the consultant/specialists. We do not, however, consider this to be the correct kind of approach to the problem. The first thing that should be done is to estimate the incidence of the disease *directly, in the profession as a whole*. Only this could prove how typical are the occupational differences—and apparent similarities—demonstrated here among the *members of this Society*. And only in this way could the relevant associations and relationships of the disease be adequately investigated.

An appropriate field survey would be necessary, and this could conveniently do more than determine the incidence rates in different sections of the profession. Questions could be designed to explore such differences of incidence as may be discovered, in terms of current thinking on the pathogenesis of coronary heart disease, and in terms of the structure of the profession and the different roles within it. To be most fruitful, of course, such a survey should also be based on *ad hoc* case study—for example, of the work, habits, and social relations of general practitioners, of different ages, in different types of practice, recently recovered from "coronary thrombosis," and of "controls." The opportunity should be taken to disentangle the antecedents of coronary heart disease among doctors, whether or no it is confirmed to be commoner in one group of them; it is important enough in all.

Various methods of inquiry are open. It may not be practicable (though it need not be entirely ruled out) to compare the prevalence of the chronic atheroma and the acute thrombosis in different sections of the profession, a study that would be particularly valuable for the understanding of the fundamental processes of coronary heart disease (Morris, 1951). Nor would doctors make easy subjects for investigations of the psychological components of the disease; though such matters as hours of sleep, load of work and responsibility, and the response to upsetting situations are "psychological" as well as "physical." (It is remarkable how little study has been reported on the nature, predispositions, and consequences of medical practice, and on such matters as the emotional satisfactions and stresses involved in different types of professional life.) The distribution of the disease in town and country, and different types of town and different parts of the country, should be examined. The influence of "constitution," of family history in different sections of the profession, and of physique (Gertler, Garn, and White, 1951) could be investigated, together with their possible relation to the "environmental" factors. Considerably more clinical detail than is presented here can be collected. Records of the war history (both wars), as well as post-war experiences of patients and "controls," are needed. Studies of the blood lipids, at present so promising, though where they are leading is still clouded in mystery, may be possible, with a long-term follow-up; and assessments of diet and nutrition. The association and dissociation of other disorders and coronary heart disease might be investigated (see Gregg, 1950). Analogous studies might be carried out on the incidence among doctors of such conditions as "essential" hypertension, duodenal ulcer, and of course cancer. In brief, the occasion might be taken for the profession to examine itself, medically and socially.

Finally, before leaving this discussion of coronary heart disease in medical practitioners, it may be worth pointing out that this study has been made with simple methods and in a small—though well-defined—"population." The number of men studied, in fact, might be found in a town of 30,000 or 35,000 people, a town the size of Hereford, or Taunton, or Airdrie. In view of the growing interest of the medical officer of health in epidemiological inquiries on the non-infectious diseases, it is reassuring to see that they may well be usefully carried out with modest resources, as is already well known to be possible in the acute infections (Paul, 1950). The present inquiry, by its reference to a

well-defined "population," by its study of a "cohort," and by its use also of some clinical approaches, has yielded elementary information on the incidence and prevalence of one of the most serious diseases in the population. It has raised questions on the natural history in middle age, and has provided some facts on the life of its victims. It has given some indication of what would be involved in a field survey of the principal cardiovascular diseases, and has suggested one approach to the investigation of causes, through its uncovering of what may be an "experiment of opportunity."

PART III: THE DISEASE IN MEDICAL PRACTITIONERS AND IN OTHERS

There is a widespread impression that doctors suffer more from coronary heart disease than the rest of the population, though the papers on the subject have been divided (Osler, 1910; Boas and Boas, 1949). This impression is based on clinical experience and mortality rates from England and Wales and the United States (Registrar-General, 1938; Dublin and Spiegelman, 1947). The clinical evidence is of doubtful value. Quite simply, in order to determine whether there is any difference in the experience of doctors and others, it is necessary to know, for a definite period of time, the ratio

$$\frac{\text{No. of cases of coronary heart disease in doctors}}{\text{No. of doctors among whom these cases are occurring}}$$

and it must be possible to compare this with the corresponding ratio

$$\frac{\text{No. of cases in other people}}{\text{population in which these are occurring}}$$

In both it is necessary to know the sex and ages of those in the numerator and denominator. (The problem is exactly the same as in comparing the experience of one group of doctors with that of another.) Many of these facts are not usually available in clinical work, and impressions based on the numbers of doctors seen by any individual or in any clinic are apt to be quite inaccurate. Probably the least reliable impressions are those of distinguished physicians who may have a quite disproportionate number of doctors in their personal practice, and generalize from that. The mortality rates present other kinds of problem: in particular, the latest from this country are for 1930-2, as the war prevented the holding of the 1941 census and the publication of the traditional Decennial Supplement on Occupational Mortality based upon it. The clinical recognition of "coronary thrombosis" was not yet very common in this country in 1930-2. Moreover, as indicated in Part II of this paper, it may not be sufficient to group all medical practitioners together as was done in those death rates.

Since the present inquiry forms part of a wider investigation which includes a number of non-medical groups, it provides an opportunity for reconsideration of this question which has caught the imagination of physicians on both sides of the Atlantic. The non-medical groups include professional, scientific, technical, executive, and clerical grades of the Civil Service (established men only), a large number of schoolmasters, several grades of Post Office workers, the Metropolitan Police, building workers of the London County Council, drivers, conductors, and several other grades of the staff of London Transport Executive, and various smaller professional, clerical, and industrial groups. In all, the diagnoses made among a miscellaneous group of about 200,000 men for 1949 and/or 1950 can be considered here—that is, a number that might be found in a city of a million people or so. Between 35 and 40 years of age there are relatively few cases, and after 60 the conditions of service in the various organizations and grades differ so considerably that it is not always practicable to define who remains and why. The experience of men aged 40-59 years, will therefore be considered and, as before, first attacks of the disease will provide the main material for comparison. The information was specially obtained for the purposes of

this research by the various occupational health services in their examinations of workers (especially those absent from work for any length of time), as well as from the certificates given by general practitioners, hospitals, and consultants and sent to employers. A particular check was kept so far as possible on the "suspect labels" of "myocardial" disease, etc. The main findings are presented below.

Incidence of Coronary Heart Disease

Standardized Rate per 1,000 Men Aged 40-59

General practitioners	7.1 (Table XI)
Other doctors	3.3 "
Miscellaneous, non-medical group ..	2.5

Comparing, first, the experience of the "other doctors" and the non-medical group, it may be said that an incidence of 3.3 is little higher than 2.5. If, therefore, the experience of this non-medical group is at all typical, it would appear that doctors in this country are diagnosing first attacks of coronary heart disease about as often in the population as a whole as they are diagnosing it in those members who are not full-time general practitioners.

Here we must digress to emphasize what such figures mean. When an attempt is made to compare the incidence of a disease in one group with that in another, what is in fact being compared is the incidence of the *diagnosis* of the disease in the two groups. Now there is no justification whatever for supposing that the level of diagnosis of coronary heart disease is the same in the medical profession as in the public, and therefore no justification for assuming that because similar rates are here reported the true incidence is similar. These medical rates almost certainly include a high proportion of all the coronary heart disease that produced symptoms among the "other doctors." In the miscellaneous non-medical group it is not possible to say more than that the methods of diagnosis and collection adopted may have resulted in an equally high proportion of coronary heart disease being recognized and recorded; but quite likely it did not.* If many of the cases in the non-medical group are being wrongly called coronary heart disease, there may in fact be some real excess of it among "other doctors." On the other hand, if many cases of coronary heart disease among the miscellaneous group are being overlooked, it may well be that these "other doctors" have a lower incidence than the population as a whole, in so far as this is represented by the group being studied.

The fatal first-attack rates show similar trends, and so do the total mortality rates (Fig. 13). In the following, the rates for England and Wales are estimated from the pro-

FIG. 13.—Coronary heart disease in medical practitioners and in others. Men aged 40-59, inclusive. A=General practitioners (Category 1), 1947-50. B=Other doctors (Categories 2+3+4), 1947-50. C=Miscellaneous non-medical group, 1949-50. D=England and Wales, Civilian Population, 1950 (provisional). A and B held Medical Sickness, Annuity and Life Assurance Society Immediate Benefit Policies.

visional figures for 1950, kindly supplied to us by the Registrar-General (1952, personal communication), and are based on the Sixth Revision of the International List of the Causes of Death. (One effect of this revision is that deaths from myocardial infarction are now included with coronary disease.) These national figures are used because the total

*The early case-fatality ratio—that is, the proportion of first attacks that were rapidly fatal—is higher among this miscellaneous group than among these "other doctors." But as the advantage of the "other doctors" may partly be due to better treatment, as well as to better diagnosis with the recognition of milder cases, and the relevant number of "other doctors" variously affected is small, this aspect cannot be satisfactorily discussed.

mortality is required, and there is no means of assessing how many of the deaths from coronary-heart disease that do not occur in the first clinical attack will be recorded by employers in the above non-medical group, since the first (non-fatal) attack may result in a change of employment. The rates of medical practitioners are for the Society's members in 1947-50, and they include deaths in later as well as in first attacks.

Mortality from Coronary Heart Disease

Standardized Rate per 1,000 Men Aged 40-59

General practitioners	2.4
Other doctors	1.5
Males, England and Wales	1.4

It should be remembered, moreover, in comparing the 1.5 and 1.4 that even under 60 years of age there still are quite a number of deaths ascribed to "myocarditis," etc., in the Registrar-General's Tables, which are not included in the 1.4; among the medical practitioners the number so diagnosed is quite negligible.

The problem is very different when comparing the experience, and particularly the incidence, of the *general-practitioner* members with the non-medical group. If the figures presented here for the non-medical group bear any relation to reality, it may well be that these general practitioners have a higher incidence than that group. Moreover, if these miscellaneous professional, clerical, and industrial workers are at all representative of men in their age groups, and if, similarly, the general-practitioner members of this Society are typical of all general practitioners, the higher incidence reported here may be evidence in support of the common impressions on the subject. The differences noted in these total mortality rates are smaller than for the incidence, owing possibly to recent changes in the incidence of first attacks, fatal and non-fatal, among general practitioner members. If this is the reason it may be an illustration how recent variations in incidence rates may not appear simultaneously in the corresponding total mortality rates, which, in a disease that is often chronic, must show a time-lag and include deaths from illnesses originating over a long period.

Here this problem of a possible difference between medical practitioners and the rest of the population must unsatisfactorily be left. It is an interesting question, but not at present one with a great deal of meaning. Eventually it may be practicable to carry out large-scale diagnostic surveys of coronary heart disease in the population, with standardized methods, and in the course of these it may be possible to answer this particular question.

Summary and Conclusions

A study was made of clinical coronary heart disease diagnosed among over 6,000 male medical-practitioner members of the Medical Sickness, Annuity and Life Assurance Society, Ltd., aged 35-64, who held "immediate" non-cancellable sickness insurance, providing benefit, on receipt of a medical certificate, for periods of incapacity to work which last seven days or more. The Society also has knowledge of all deaths in its membership, even when these occur after an illness of less than seven days. Apparently about a quarter of the male doctors of the country in the ages studied belong to the Society, and hold this type of insurance. The report deals only with these doctors, and no information is available about the doctors who do not belong to the Society (or about those who do belong but have other kinds of policy). A full medical examination is given to all applicants for membership of the Society.

The average annual incidence of first clinical attacks of coronary heart disease ("coronary thrombosis"—acute myocardial infarction—and angina pectoris) in

these medical practitioners during 1947-50 increased with age, to reach 16.6 per 1,000 at 60-64 years.

The coronary death rate in 1947-50 similarly rose with age to 7.4 per 1,000 at 60-64 years; and it accounted for about a third of all mortality in these insured medical practitioners in each five-year age group. The deaths were mainly concentrated in the first attack; in 1940-50, inclusive, 56% of all deaths from coronary heart disease among the members aged 40-64 were "sudden," occurring in the first six days of the first clinical attack, and another 14% took place in the remainder of the first month. Coronary deaths occurring after the first month of the first attack accounted for only 30% of the total coronary mortality among these medical practitioners in the eleven years 1940-50.

On current experience, the probability that the individual practitioner member under 45 years of age who has not yet been attacked by it will be attacked by clinical coronary heart disease before he reaches 65 are about one in five, or 20%. The chances that the individual practitioner under 45 years of age will die of it are about one in fourteen, or between 7.1% and 7.5%.

In 1950 the prevalence of coronary heart disease among the members aged 60-64 years was about 9%. The 9% was made up of rather more than 4% "active prevalence"—men who were disabled from work for at least a week during the year because of coronary heart disease; and rather less than 5% with "latent" disease—men who had suffered from the disease before 1950, and were alive in 1950 but not incapacitated from work on account of it during that year for as long as a week.

The prognosis for life in "coronary thrombosis" was examined from the onset of the first clinical attack. About 30% of all these men aged 40-64 experiencing first attacks died in the first six days of the first attack—the "sudden" deaths; another 8% died in the remainder of the first month, making 38% in all in the first month. Thereafter the picture is quite different, with 2% dying in the remainder of the first year, and an average of about 2% dying annually in the next six years. Men aged 40-49 at the date of onset of the first clinical attack had apparently a rather lower mortality during the few years that can be observed than those aged 50-64. Of the men who survived their first attack of "coronary thrombosis" about half had no further absence for coronary heart disease (or its complications) that lasted as much as a week during the next six years. The average time lost from work for coronary heart disease during the next six years by men who survived their first attack was about four weeks per man per year. This figure makes no allowance for part-time work, etc.

The outlook for life of men first presenting with *angina pectoris* was very much better than for the others. During the five years from the date of onset about 11% of them died; their prognosis for life was therefore about the same as in men first presenting with "coronary thrombosis" who had survived the first month, with its 38% mortality.

The mode of first presentation of coronary heart disease in these medical practitioners aged 40-64 was about 24% as "sudden" death; 55% as less severe "coronary thrombosis"; 17% as the relatively benign *angina pectoris*; and 4% of miscellaneous "coronary insufficiency," etc. The proportion of *angina pectoris* increased from 12% at 40-44 to 22% at 60-64; the proportion of the intermediate group of less severe "coronary thrombosis" was smaller in the older men;

the proportion of "sudden" deaths as first manifestation changed little with age.

The membership of the Society holding these immediate sickness insurance policies was sampled and divided into four occupational categories: full-time general practitioners, full-time consultants/specialists, "G.P.-Specialists," and public officials. The incidence of first attacks of coronary heart disease in 1947-50 was twice as high among the full-time general-practitioner members aged 40-64 as in the rest. The excess incidence was seen in each five-year age group, in first attacks that were soon fatal as well as in those that were not, and in each of the four years 1947-50. When the "G.P.-Specialists" were added to the full-time general practitioners, the incidence in this composite group was 1.8 times the incidence in the remainder. There was little difference between the rates of the full-time specialists, the "G.P.-Specialists," and the public officials, but the numbers in each of these three categories were very small.

Evidence about 1940-6 is incomplete. Such information as is available suggests that there was little, if any, excess among the general-practitioner members during the war. There is no information on the situation before the war.

Finally, the experience of these medical practitioners was compared with that of a large miscellaneous group of men in the civil services, in the professions, and in industry. The incidence of coronary heart disease in this non-medical group was well below that of the full-time general practitioners, and resembled that of the other doctors. A comparison with the provisional mortality rates from coronary disease among the males of England and Wales in 1950 gave similar results.

We are obliged to many for helping us in this investigation: to the Directors of the Medical Sickness, Annuity and Life Assurance Society, Ltd. for allowing us free use of their existing records and for setting up the elaborate additional recording apparatus that was necessary; to Mr. E. A. J. Heath, manager and actuary of the Society, and to other members of its staff; to the Registrar-General and the various chief medical officers and their medical and lay colleagues for providing us with the information from which the non-medical rates of Part III were calculated; to the officers of the Accountant General's Department of the Ministry of Health, and in particular Mr. A. A. Greneski and Mr. H. W. Meyer; to the chief medical officers of the Department of Health for Scotland and the Ministry of Health and Local Government, Northern Ireland; to Dr. L. I. Dublin; to Messrs. J. and A. Churchill Ltd. and Mr. B. S. Stanton, Editor of the *Medical Directory*; to Professor A. Bradford Hill, for most valuable criticism and advice on Part II; to Mr. R. D. Clarke for generous help on the whole paper; to colleagues and friends for many suggestions; and to the secretarial staff of the Unit for much practical assistance.

APPENDIX 1

The Individual Practitioner's Chances: Methods of Calculation

To calculate the probabilities shown by Tables III and IV it was necessary to construct two life tables showing the subsequent history of a hypothetical body of 1,000 practitioners coming under observation at exactly age 35 (the lowest age in both Tables III and IV) as follows:

Chance of Getting Coronary Heart Disease (Table III)

At each age from age 35 to age 65 the life table shows:

l_x , the number at the beginning of the year of age x to $x+1$, not yet clinically attacked by coronary heart disease.

c_x , the number (out of l_x at the beginning of the year of age) clinically attacked during the year of age (these must all be first attacks on account of the definition of l_x).

d_x , the number (out of l_x at the beginning of the year of age) who die during the year of age (except on account of coronary heart disease, in which case they would be already included in c_x).

The number of "living," l_x , are thus subject to two mutually exclusive causes of reduction—and it will be seen that $l_x - c_x - d_x$ gives l_{x+1} , the number living, and not yet clinically attacked by coronary heart disease, at the beginning of the year of age $x+1$ to $x+2$.

Table III shows the probabilities of being attacked for the first time between age x and age y in the form of numbers per 1,000 at age x . These probabilities are given by the formula

$$\frac{c_x + c_{x+1} + \dots + c_{y-1}}{l_x} \times 1,000$$

To construct the life table, estimates were needed of (a) the rate of first attack in a population of lives not yet attacked, and (b) the rate of death from causes other than coronary heart disease in the same population. For the reasons given in the text, the first attack rate was obtained from data for 1949–50. The number of lives attacked in any given year was estimated from the "total prevalence" figures in Table V and subtracted from the total mean population to give the number of lives not yet attacked. The "non-coronary" death rate among lives not yet attacked was assumed to be the same as the "non-coronary" death rate among the whole group investigated, no closer estimate being practicable. This rate was based on data for 1947–50, since no important changes in death rate had taken place in this period and the larger figures thus available gave a smoother progression of rates with age. This "non-coronary" death rate was thus in fact, though not in theoretical basis, the same as the "non-coronary" death rate used in the life table leading to Table IV.

The rates obtained were those for five-year age groups. To obtain rates for individual ages the group rates were plotted and a smooth curve drawn passing through or close to these points so as to estimate the trend in terms of individual ages, the rates for which were read off. The life table was then calculated.

Chance of Dying from Coronary Heart Disease (Table IV)

At each age from age 35 to age 65 the life table shows:

l'_x , the number living at the beginning of the year of age x to $x+1$, whether already clinically attacked by coronary heart disease or not.

d'_x , the number, out of l'_x at the beginning of the year of age, who die from coronary heart disease during the year of age.

d''_x , the remainder of the deaths during the year of age.

The number living at the beginning of the year of age $x+1$ to $x+2$, l'_{x+1} , is thus given by $l'_x - d'_x - d''_x$.

The probabilities shown by Table IV (in the form of numbers per 1,000 at age x) of dying from coronary heart

disease between age x and age y (whether already clinically attacked at age x or not) are given by the formula

$$\frac{d'_x + d'_{x+1} + \dots + d'_y}{l'_x} \times 1,000$$

To construct the life table estimates were needed of (a) the rate of death from coronary heart disease, and (b) the rate of death from all other causes, in both cases in the total population, whether attacked or not. These were obtained from data of 1947–50 as mentioned in the text. The rates obtained were for five-year age groups and rates for individual ages were found by the process described above.

There is a theoretical objection to this life table, and hence to Table IV, in that the body of lives among whom rates were actually observed is subject to the addition of new entrants who have just passed a medical examination satisfactorily and who therefore have not yet been clinically attacked. The practical effect of this objection must, however, be small in this investigation because the number of new entrants above, say, age 40 is extremely small in relation to the existing membership at these ages. Furthermore, the practical effect, if any, of the existence of a small number of recently selected lives is to underestimate slightly the death rates observed, and thus Table IV cannot on this account exaggerate the position.

A further difficulty, which applies to both life tables, is that where more than one force of decrement is involved the process of passing from the observed rates to the numbers in the life table is theoretically more complex than where a life table showing the single decrement of "death from all causes" is concerned. This complexity arises from the fact that the forces of decrement considered are operating simultaneously. In the second life table, for example, a death (in d''_x) at time t between age x and $x+1$ is dependent on the same life not having died of coronary heart disease between age x and $x+t$. The details of a theoretically correct process depend on the form of the original observed rate, and the considerations involved are fully discussed by Bailey and Haycocks (1946). In the present inquiry the scale of the investigation and the progression and actual size of the rates observed made it possible to apply the original rates for individual ages directly to a radix—that is, the hypothetical body of "lives" whose subsequent history is shown by the life table—of 1,000 at age 35 without affecting the final figures presented. In other circumstances this would not necessarily be possible.

APPENDIX 2

Prognosis: Methods of Calculation

As explained in Part I of the text under "Prognosis," all calculations were based on the 243 first absences for coronary heart disease starting in the years 1940–50, inclusive, among men aged 40–64 inclusive. These 243 cases were divided into three groups: 192 which presented in the first absence as "coronary thrombosis," 42 which presented as angina pectoris, and 9 which presented as "coronary insufficiency," etc. (Some of the cases presenting as angina pectoris had further absences where the condition was diagnosed as "coronary thrombosis," but this did not affect the grouping which was determined by the diagnosis in the first absence.) Attention was mainly focused on the 192 cases of "coronary thrombosis," because the number of cases of angina pectoris gave little scope for analysis. The other nine cases were ignored in this context.

Prognosis was considered from three points of view: (1) *Prognosis for life and death*—the chance of dying of coronary heart disease in a given time, measured from the beginning of the first absence from work on account of it. (2) *Prognosis for further absence*—the chance of being absent again because of coronary heart disease in a given time after the end of the first absence. (3) *Prognosis for work*—the average amount of time lost from work because of coronary heart disease, in a given time after the end of the first absence.

All three concepts were explored with the cases presenting as "coronary thrombosis"—the second and third applying, of course, only to the men who could be followed until they returned to work after the first absence. There were 107 such men out of the original 192; 80 died in the first absence, and five could not be followed to the end of it. For angina pectoris it was only possible to attempt prognosis for life and death.

It was not possible to follow all cases for an equal length of time, if only because an arbitrary date had to be chosen at which observations ceased (June 30, 1951), and the cases arose at different times during the 11-year period. The method adopted was to measure time for each case from the beginning of the first absence, or from return to work after the first absence, according to the particular type of prognosis considered. The observation time was broken up into periods of a year (except for the first year in prognosis for life and death, which was divided into different intervals—see below), and the experience in each year was considered for all those cases which were still under observation at the beginning of the year. The proportion surviving, for instance, to the end of the first year was calculated from the first year's data. From the second year's data the proportion of these survivors who reached the end of the second year was calculated. The product of the two proportions gave the proportion of the original number who survived to the end of the second year, and so on. A cumulative product was thus obtained which gave the proportion surviving up to the end of any given number of years from the beginning of the first absence.

The principle was also adapted to calculate the proportion of those returning to work who had a further absence in a given number of years after such return, using the proportion having further absences in individual years.

It was necessary to consider the experience year by year. An alternative would have been to calculate the proportion dying before the end of a given year by dividing the number of deaths in that time by the total number of persons observed (suitably adjusted for lapses of observation). This would, however, give undue weight to the experience of the first few years, when the numbers under observation are far greater.

In any given year (or shorter period) expressions had to be found which would give good estimates of the proportion dying (and hence the proportion surviving), or the proportion having a second attack, in the year, allowing for the fact that it was not possible to observe everybody for the whole year.

Reasons for Lapse of Observation.—The reasons why men could not be observed for a whole year were as follows: (1) Their policies might terminate during the year, on reaching the age of 60 or 65. (2) The end of the observation period (June 30, 1951) might fall within the year. (3) They might die from (a) coronary heart disease or (b) another condition.

Prognosis for Life, and Death

The percentage dying in the year from coronary heart disease was calculated from the following formula:

$$\frac{\text{No. of persons dying during the year from coronary heart disease} \times 100}{X+Y+Z}$$

Where X = one year each for all those alive and under observation for the whole year.

Y = the sum of the observed parts of a year for those in 1, 2, or 3b above.

Z = one year each for those in 3a above who would have been followed for the whole year had they lived; and for the rest, the sum of the parts of a year for which they would have been followed had they lived.

The formula had to be slightly modified in the first year, which was divided into three unequal periods—the first six days, the remainder of the first month, and the rest of the year. This decision was adopted because by far the greatest

part of the mortality in the first year (and indeed in the whole natural history of the disease under 65 years of age) occurs in the first few weeks—in fact, in the first few days.

In the first six days $Y=0$ because no absence occurred within six days of the policy terminating, and, since no absences starting in 1951 were considered, could not occur within six days of June 30, 1951. For the same reason Z is all deaths from coronary heart disease. In this case, then, $X + Y + Z$ is simply all absences starting in the period.

Similarly, for mortality in the rest of the first month, no absences started within a month of termination of the policy and could not occur within a month of June 30, 1951. $X + Y + Z$ here is all survivors of the first six days.

In the rest of the first year it was necessary to convert all periods of observation, which had been calculated in decimals of a year, to decimals of eleven months.

After the first year there were no special difficulties.

Calculations were made for each 5-year age group from 40–64, age always being reckoned from the start of the first absence.

Prognosis for Further Absence

This applies, of course, only to those who returned to work after the first absence, and there is no problem of unequal periods in the first year. Numbers were not large enough to attempt the calculation for the men with angina pectoris.

In each year after return to work the percentage of survivors who, not having had a further absence, started one in that year was calculated according to the formula:

$$\frac{\text{No. of persons starting a second absence in the year} \times 100}{U+V+W}$$

Where U = one year each for all those who, not having had a second absence before the year in question, were alive and under observation for the whole year, whether or not they started a second absence during the year.

V = for those who, not having had a second absence before the year in question, were alive but could not be followed for the whole year for reasons 1, 2, or 3b above—the sum of the observed parts of a year, whether or not they started a second absence during the year.

W = for those in 3a above who did not have a second absence before the year in question, and who died during the year from coronary heart disease—one year each for those who would have been followed to the end of the year had they lived and, for the rest, the sum of those parts of the year for which they would have been followed had they lived.

Schematically the matter may be presented thus:

"Further absence" includes all cases in which death occurred after return to work from the first absence, even when the fatal illness lasted less than seven days, and was therefore not recorded as an absence.

Prognosis for Work

As for "Prognosis for Further Absence," this applies only to those who returned to work after the first absence and to the "coronary thrombosis" group.

In each year after return to work the percentage of time lost from coronary heart disease was calculated according to the following formula :

$$\frac{\text{Total time lost from work on account of coronary heart disease in the year} \times 100}{\text{Total possible time at work in the year}}$$

where the "total time lost" is the sum of all periods of absence during the year from coronary heart disease among those under observation at the beginning of the year (including the remainder of the year for those who died during the year); and "possible time" is what would have been possible if there had been no absence—that is $X+Y+Z$ of "Prognosis for Life and Death" if calculated from return to work.

"Time lost" does not refer to the actual working hours. The data merely give the days lost, and these are converted to fractions of a year.

Throughout these calculations exact dates at which absence began and ended, and policies terminated, permitted accurate calculations of the periods of exposure to risk and time off work. The methods would of course not be applicable without adjustment where such complete information was not available. All fractional periods were worked in decimals of a year correct to two decimal places.

The fact that in "coronary thrombosis" a very large proportion of deaths occur in the first few days of the first absence means that what at first seemed a considerable body of data did not give as much information about prognosis for life and death as had been hoped. The information about how prognosis varied with age, for instance, was disappointing. Thirty per cent. of all first attacks result in death within six days and 38% within a month, but, of the 91 recorded deaths amongst the 192 cases presenting as "coronary thrombosis," 74, or about 80%, occurred within the first month.

A disease, like pulmonary tuberculosis, in which the chance of early death is relatively small, and in which the deaths are more evenly spaced in time, would give greater scope for the methods used.

APPENDIX 3

Independent Categorization of Samples of Membership, and of Men having First Attacks of Coronary Heart Disease, from the Records of the National Health Service

The following are the results of the two checks that were applied to test the validity of the categorizations already made (and summarized in Table XI) from the *Medical Directory* of 1946, 1948, and 1949.

Category from <i>Medical Directory</i> (1)	General Practitioners		Hospital Staff	
	No. Checked on N.H.S. Lists for General Medical Services (2)	Proportion Found on N.H.S. Lists (3)	No. Checked on N.H.S. Lists for Hospital Service (4)	Proportion Found on N.H.S. Lists (5)
General practitioners, Category 1	485	91%	122	1.6%
Consultants/specialists, Category 2	186	1.6%	87	85%
G.P.-Specialists, Category 3	123	88%	123	66%
Public officials, Category 4	68	13%	68	2.9%

Column 1—The four main categories as described in the opening of Part II of this report.

Column 2—All in the samples aged 45–64, and all cases of first attack alive and at work after July 5, 1948, were checked on the general medical services lists of N.H.S.

Column 3—The proportions of those in column 2 who were found to be providing general medical services under the N.H.S. Act. Most of the public officials who were providing such service were clearly doing so for other members of their own staffs.

Column 4—It was impracticable to classify hospital service as "specialist" or otherwise. The following general practitioners are included in the 122 categorized from the *Medical Directory* as general practitioners who were now checked for hospital service: all in the samples who were not found in the general medical services lists; all in the samples who were resident in Scotland and Northern Ireland; all G.P.s who had first attacks of coronary heart disease in 1947–50 and who were alive and at work after July 5, 1948. The 87 consultants/specialists whose names were now checked included all so categorized who were not on the staff of teaching hospitals; and all the relevant cases of coronary heart disease.

Column 5—The proportions of those in column 4 now found to be rendering N.H.S. hospital service. The 2 of the 122 categorized as general practitioners who were found to be under contract for hospital service were also rendering general medical services. 12 of the 41 "G.P.-Specialists" not found in the N.H.S. lists seemed to have lost their hospital appointments very recently, judging from the changes in the *Medical Directory* between 1946–9 and 1951; 27 still record these appointments in the 1951 *Medical Directory*; 2 had retired. Two "public officials" now found to be clinical specialists were also clearly continuing as public health officers: 2 of 68 is 2.9%.

HERPES ZOSTER VARICELLOSUS

BY

D. I. McCALLUM, M.C., M.B., M.R.C.P.Ed., D.P.H.

Late Senior Registrar, Department of Dermatology, Royal Infirmary, Edinburgh

In 1892 von Bókey, of Budapest, described the simultaneous appearance of herpes zoster and varicella in the same patient, and he advanced the theory that the two conditions were caused by the same virus. Seiler (1949) has estimated that the yearly incidence of herpes zoster in Edinburgh is 2 per 1,000 of the population, and that 3.8% of these zoster cases are complicated by a varicelliform eruption.

Most uncomplicated zoster cases in this region are dealt with by local practitioners, and few are referred to the Infirmary. During the period under review (1947–50 inclusive) the number of zoster cases seen was 79, of which 67 were uncomplicated, 6 suffered from involvement of the eye, and the remaining 6 cases were complicated by a generalized varicelliform eruption. Five of the cases are summarized in the Table on the opposite page, and the sixth is described in greater detail below.

Case Reports

Case 6.—A man aged 69 was suffering from haemorrhagic herpes zoster in the distribution of the ophthalmic division of the fifth cranial nerve on the right side. The condition had been present for seven days. Before the attack of

zoster his health had been excellent and there was no history of his having taken drugs of any sort. Blood examination showed no abnormality. He had never had herpes zoster or varicella previously. The day after the appearance of the zoster lesions a generalized varicelliform eruption developed suddenly. This eruption reached its maximum distribution within 24 hours, and thereafter no fresh lesions developed. He was photographed on the day he first reported, and a biopsy of a vesico-pustule on the right forearm was done by one of the doctors in the department.

Case 7.—The doctor who had done the biopsy on Case 6 complained of general malaise, anorexia, and headache 13 days later, and on the following day a typical varicella eruption developed, beginning in the scalp and on the fauces, and appearing in crops on the trunk, back, face, and arms during the subsequent three days. At its height two days later the rash was profuse, especially on the back, but by this time the constitutional symptoms had subsided. There was no previous history of herpes zoster or of varicella, although the patient had often been in contact with both diseases. He was clear of varicella lesions in 16 days.

Case 8.—The technician who had photographed Case 6 complained of general malaise and had the typical features of varicella 15 days after his one and only contact with Case 6—that is, two days after Case 7 had developed varicella.

FIG. 1.—Case 3, showing haemorrhagic herpes zoster of L1 and L2 and the varicelliform eruption of trunk and limbs.

Seven days later an eruption of herpes zoster appeared over the area of distribution of the twelfth thoracic and first

The technician did not touch Case 6 nor did he handle his clothing. Here again there was no previous history of herpes zoster or of varicella. The rash cleared in three weeks.

Case 9.—A doctor, with whom Case 7 had lunched on several occasions between the first and tenth days of the incubation period of his varicella, developed severe neuralgic pains in the right lumbo-sacral region two days after Case 7 developed varicella—that is, 15 days after Case 7 had been in contact with Case 6.

lumbar nerves on the right side. There was no actual contact by touch between Cases 7 and 9. The doctor in question had often been in contact with cases of herpes zoster and of varicella in the past without contracting either disease, but had not recently been in contact with any other known possible source of infection.

The Diagram illustrates the relationship between the primary zoster and the secondary varicelliform eruption in Case 6 and the spread of infection to three other individuals.

Laboratory Investigation

Histology.—Biopsies were taken from the edge of the zoster eruption and from a secondary vesicle on the trunk in Case 3 and from a secondary vesicle on the forearm in Case 6 (Figs. 2 and 3). The histological features in all

Summary of Five Cases of Concurrent Herpes Zoster and Varicella

	Case 1	Case 2	Case 3	Case 4	Case 5
Sex and age . .	Male; 67	Male; 82	Male; 75	Male; 64	Male; 79
Distribution of zoster	C3, 4, and 5 on left side	Trigeminal nerve on left side	L1 and L2 on left side (Fig. 1)	7th nerve rt. side. Ramsay Hunt syndrome	C3 on left side
Interval between development of zoster and varicella	2 days	1 day	2 days	1 day	Less than 4 days
Previous history of zoster or varicella	Nil	Nil	Nil	Nil	Nil
History of contact with cases of zoster or varicella	"	"	"	"	15 days' contact with a convalescent zoster case
General health	Suffered from chronic lymphatic leukaemia	Diabetic patient	Chronic lymphatic leukaemia treated with x rays	Good	Very good
Duration of zoster eruption	6 weeks	15 days	7 weeks	Residual facial palsy 7 months later	15 days
Duration of varicella eruption	14 days	12 "	18 days	15 days	8 "

FIG. 2.—Case 6. Histopathology of a varicelliform lesion from the anterior aspect of the left forearm. The stratum corneum is intact, and immediately subjacent to it and to the stratum granulosum a thin layer of degenerated rete cells is visible. The basal layer has disintegrated, with the result that balloon cells, giant cells, and cellular debris lie directly on the upper dermis. H. and E. ($\times 60$.)

FIG. 3.—Case 6. Histopathology of a varicelliform lesion from the anterior aspect of the left forearm. The cells forming the floor of the bulla show varying degrees of degeneration. Intracellular oedema gives rise to the appearance of ballooning of the cells (A); several so-called giant cells (B), consisting of aggregations of degenerated nuclei surrounded by a variable quantity of cytoplasm, are prominent. The infiltrate consists of polymorphs and, to a less extent, of lymphocytes. H. & E. ($\times 450$.)

three sections show an intra-epidermal bulla, the roof of which is formed by stratum corneum, stratum granulosum, and the upper part of the degenerated rete mucosum. It is clearly demarcated laterally from the adjacent epidermis by a few rows of flattened degenerated rete cells. The base is composed of degenerated and disorganized rete and basal cells, around which there is an infiltration of polymorph leucocytes and lymphocytes. In this area there is intercellular and intracellular oedema, giving rise to the appearance of ballooning of the cells, and several so-called "giant cells," consisting of aggregations of degenerated nuclei surrounded by the remains of the cytoplasm of these cells, are apparent. The bulla fluid contains some of these balloon cells, giant cells, and leucocytes. In the upper part of the dermis there is oedema, with a well-marked polymorph and lymphocytic infiltrate, particularly in the perivascular situation.

Bacteriology.—On admission 10 ml. of blood was withdrawn and fluid was collected from bullae on the groin and thigh in Case 3. Large numbers of elementary bodies were demonstrated in the bulla fluid by the methods of Weiss and of Paschen. The bulla fluid was diluted and set up for complement fixation against three sera derived from known severe cases of herpes zoster, including serum from Case 2, and against three normal sera. The antigens in the vesicle fluid combined with the antibodies in the known positive sera to fix 2 M.H.D. of complement when the sera were diluted 1/16. No fixation took place with the normal sera. No antibodies were demonstrated in the patient's serum, against his own bulla fluid, or against fluid from another case of herpes zoster, indicating that the patient had not at that stage produced antibodies to the herpes zoster virus.

Comment on Case Reports

In each of the six cases of herpes zoster complicated by a varicelliform eruption the herpes zoster eruption developed first, and the interval between the appearance of the zoster and the development of the secondary rash was 24 hours to four days. None of the patients had previously suffered from herpes zoster or varicella. The herpes zoster and the secondary eruptions both healed with scarring; the duration of the zoster eruption varied within wide limits, from 15 days to 7 weeks, whereas the secondary eruption, which developed to its maximum extent in 24 hours, cleared within 8 to 21 days. In each instance the secondary eruption had cleared before the primary zoster lesions. In Cases 7 and 8 the incubation period of the varicella was 13 and 15 days, respectively—that is, within the normal incubation period of varicella. The incubation period of herpes zoster is said to lie between 9 days (Kundratitz) and 21 days (Siegl); in Case 5 it was 15 days or less, and in Case 9 it lay between 12 and 22 days.

Although epidemics of zoster have been described the actual mode of spread has not yet been established. In 1900 Haslund noted that herpes zoster was often ushered in with nasal or pharyngeal symptoms, and he regarded the tonsils as the probable portal of entry. He thought that the virus was then carried by the blood stream to a posterior root ganglion and thence via a sensory nerve to the skin. Fenner (1948) has described the mode of spread of the virus causing ectromelia in mice. He has proved experimentally that the virus multiplies at the source of infection—normally minor trauma on the skin surface—and spreads thence to infect the associated lymph nodes, where further reproduction results in a blood infection or viraemia. This primary viraemia is controlled by the phagocytic action of the cells of the liver, spleen, and other tissues. When these cells have been overcome by the virus a secondary and more profound viraemia develops, resulting in the clinical condition. It is possible that a similar sequence of events occurs in zoster and varicella, the virus being neurotropic in the former disease and dermatropic in the latter.

Montgomery (1921) considers that the more probable route of entry is via the sensory nerve endings in the skin, and this view is upheld by van Rooyen and Rhodes (1940). It is difficult to conceive how this theory can find acceptance, as prior to the onset of zoster there is rarely any history of trauma over the area affected, and the application of vesicle fluid to the unbroken skin has failed to produce either local or generalized reactions or to stimulate the development of immunity. Furthermore, aberrant vesicles are seen quite often in herpes zoster, and their presence would be difficult to explain on the basis of this theory. Case 7 had been in close contact with Case 6 while doing the biopsy, but infection in Cases 5, 8, and 9, where contact was not close, was in all probability by droplet infection; and the portal of entry may well have been the nasopharynx.

Two cases in this series suffered from chronic lymphatic leukaemia, one of them having been treated with wide-field x-ray therapy six months before the zoster attack. A series of 45 such cases developing zoster following irradiation is described by Ellis and Stoll (1949).

Brief Review of the Literature

The following clinical observations have been advanced in support of the theory that herpes zoster and varicella are caused by the same virus: (a) Varicella often occurs in children in contact with cases of herpes zoster. Adults who have not previously had chicken-pox or herpes zoster are also liable to infection. (b) Herpes zoster is occasionally followed, within five days of the vesicular phase, by a generalized varicelliform eruption (see Cases 1–6). (c) Cases of herpes zoster associated with a varicelliform eruption are not infrequently followed by cases of varicella in contacts, the incubation period being 12–16 days (Cases 7 and 8). (d) A few cases have been reported in which varicella has been followed by herpes zoster in contacts (Case 9).

A common origin for the two diseases is supported by the experimental work of Lipschütz and Kundratitz (1925) in Vienna and of Bruusgaard (1932) in Oslo. These authors reported that when infants or young children were vaccinated with zoster vesicle fluid varicelliform lesions developed locally around the site of inoculation; in a few cases a generalized varicelliform eruption made its appearance, and some of the contacts of these cases developed varicella. Cross complement-fixation reactions have been demonstrated between the serum of convalescent herpes zoster cases and the vesicle fluid or crusts of varicella cases, and vice versa, important work in this respect being that of Netter and Urbain (1924) in France and that of R. T. Brain (1933) in this country. Hassko *et al.* (1938) were unable to confirm these findings, and Thomsen (1934) failed to demonstrate any fixation between zoster serum and varicella antigen in 83 cases, the converse reaction with varicella serum and zoster antigen being also negative.

R. T. Brain considers that zoster may be regarded as a neurotropic modification of the dermatropic virus of chicken-pox. He points out that the virus in question most readily attacks young children who have no natural immunity, giving rise to the characteristic eruption of chicken-pox in varying degrees of severity, some of the milder cases passing unnoticed as subclinical infections. In either event the virus is widely disseminated throughout the body and must reach the central nervous system, where it may persist, without causing symptoms, for many years. After a short or long interval the dormant virus is provoked to activity by some autogenous factor or as the result of trauma, a toxic drug, or other infection.

Chicken-pox is a common disease and herpes zoster is relatively common, and those who uphold the dualistic theory contend that their association is not more frequent than might be expected in the case of any two diseases whose aetiology is quite distinct. In favour of this view the following points have been advanced: (a) Herpes zoster has often been described in patients who have had varicella

at an earlier date, and it does not therefore appear that a high degree of immunity exists between the two diseases. (b) The experiments of Lauda and Stöhr (1926) did not support those of Lipschütz and Kundratitz. They inoculated 55 children with herpes zoster vesicle fluid, but failed to obtain a positive local reaction in a single case. Nevertheless, three of the children developed varicella 14 days after the inoculation. (c) Zoster has been described in isolated communities where varicella is unknown, as in Cantor's (1921) report on Christmas Island and Woolley's (1946) report on three cases on Tristan da Cunha. The numbers involved in both these instances were very small, and so the reports should be treated with reserve.

It is still undecided whether the two conditions are due to the same virus, to distinct but antigenically similar viruses, or to a mutation of a reversible nature in the structure of the organism. Under the electron microscope the virus of herpes zoster is indistinguishable from that of varicella; from the clinical and pathological viewpoints this organism has an affinity for skin and nerve tissue. In children and in adults who have not previously had either disease or have not been exposed to subinfection of the virus, the tendency is for an infective dose of the virus to result in varicella, as a result of which a high degree of immunity to the organism is usually established. In the majority of adults repeated exposure to and subinfection by the virus seem to result in partial immunity of the individual. W. Russell Brain (1931) considered that the sensory neurone had a tissue immunity feeble than that of other parts of the body, or that its immunity might be temporarily diminished by a preceding lesion, so that an infective dose of the virus in adult life tended to produce herpes zoster.

Summary

Six cases of herpes zoster varicellousus are described. In one of these cases two contacts developed varicella within the incubation period of that disease, and during the incubation period one of these two varicella cases was responsible for conveying the infective agent of herpes zoster to another contact. The literature on the subject is briefly reviewed. It is concluded that herpes zoster and varicella are very closely allied; the definition of the exact relationship of the organisms must be left to the bacteriologist.

I wish to thank Professor G. H. Percival for helpful advice in preparing this paper. Thanks are also due to Dr. R. H. A. Siwain for the bacteriological investigations and to Mr. T. C. Dodds for the histological preparations and photographs.

PULMONARY ASPERGILLOSIS FOLLOWING POST-INFLUENZAL BRONCHOPNEUMONIA TREATED WITH ANTIBIOTICS

BY

J. D. ABBOTT, M.D., Dip.Bact.

H. V. J. FERNANDO, M.B., B.S.

K. GURLING, M.D., M.R.C.P.

AND

B. W. MEADE, M.B., B.S.

(From King's College Hospital and Medical School, London)

The association of fungus infections with antibiotic therapy is now well recognized. Although many references are to be found in the American literature, few examples have been recorded in this country. We therefore think the following case of pulmonary aspergillosis is of interest.

Case Report

A housewife aged 51 was admitted on February 9, 1951, during an influenza epidemic, with a diagnosis of post-influenzal bronchopneumonia and toxic purpura. Her symptoms, which began three weeks previously, were typical of the prevalent influenza. The cough became worse, though the sputum was scanty, mucopurulent, and never blood-stained. She remained febrile, and three days before admission developed a purpuric rash.

Clinical Examination.—The patient was slightly cyanosed, dyspnoeic, and febrile—temperature 99.5° F. (37.5° C.), with a dry mouth—and obviously very ill. There were petechiae and haemorrhagic bullae on her face, arms, and legs which were considered to be typical of a "sedormid" eruption. She had taken three tablets before this rash appeared. There was slight impairment of the percussion note at the right base, and diffuse moist sounds were heard over both lower lobes. She had a regular tachycardia of 120, slight venous engorgement, and a little oedema of the ankles suggesting mild congestive failure. The blood pressure was not recorded because of bullae on the arms. A radiograph of the chest on February 9 showed obliteration of the right costophrenic angle with heavy lung shadows and only slight mottled opacities in both lower zones.

Special Investigations.—A blood count showed: Hb, 94% (Haldane); white cells, 18,000 (neutrophils 95%, lymphocytes 1.5%, monocytes 3%, metamyelocytes 0.5%); platelets, 230,000 per c.mm.; clotting-time, 5 minutes (capillary tube); bleeding-time, 3½ minutes (Duke). The urine contained: albumin, a trace; sugar, a trace on occasions; pus cells, 1–4, and red cells, 0–3, per ½ field. Blister fluid was sterile. Direct examination of the sputum on February 12 showed numerous pus cells and a few yeast forms; no acid-fast bacilli were seen. Culture yielded a heavy growth of *Bact. coli* sensitive to streptomycin and chloramphenicol, and a heavy growth of *Candida albicans*.

Progress and Treatment.—Treatment was begun at once with crystalline penicillin, 500,000 units eight-hourly. Two days later the patient was afebrile, the pulse rate had fallen, and she was much improved. On the fifth day, however, despite the absence of fresh physical signs in her chest, the temperature rose, penicillin was discontinued, and chloramphenicol was given, 3 g. initially and 0.5 g. six-hourly. By the tenth day her temperature was 100° F. (37.8° C.); she had a pleuritic pain in the right chest, auricular fibrillation had developed, and the sputum, still scanty, became purulent and streaked with blood.

FIG. 1.—Radiograph of chest (February 19) showing opacities in left upper and mid-zones.

A chest radiograph on the eleventh day (February 19) showed extensive mottled opacities in the left upper and mid-zones containing what appeared to be irregular thin-walled cavities. Streptomycin, 0.5 g. twice daily, was now given in addition to chloramphenicol. On February 20 the sputum contained numerous pus cells, with occasional yeast forms and filaments suggestive of *C. albicans*; no acid-fast bacilli were seen. Culture yielded a predominant growth of *C. albicans*. From that time the patient's condition deteriorated, and she died in coma 16 days after admission.

Post-mortem Findings

The body was that of a thin elderly woman. There were several bullae on the arms, face, and feet which did not appear infected. Both lungs were emphysematous and oedematous. The left upper lobe contained a thin-walled cavity 5 cm. in diameter which had a trabeculated lining dusted with fine white and grey particles. The rest of this lobe showed bronchopneumonic consolidation, as did the right lower lobe to a lesser extent. The pancreas showed a haemorrhagic area in the tail, with several areas of softening elsewhere. The kidneys were pale and their capsules stripped easily. On the right side there were two large recent infarcts, and on the left several smaller less recent areas of infarction.

FIG. 2.—Section through lining of cavity in left upper lobe, showing fungal mycelium typical of aspergillus. H. & E. (×320).

Histology.—Sections from the left lung showed the cavity to be lined with a densely felted layer of fungal mycelium and occasional conidia. The structure of the mycelium and conidia was typical of aspergillus (Fig. 2). Neither mycelium nor yeast forms of *C. albicans* were seen in the lung tissue. The adjacent

lung showed consolidation, with a haemorrhagic fibrinous exudate. Fragments of mycelium were found in the lung tissue throughout the upper lobe and to a less extent in the lower lobe, where there was a less pronounced exudate. Sections from the right lung showed some bronchopneumonic consolidation in the lower lobe, with fragments of mycelium in the exudate filling some bronchioles. In the pancreas there were irregular areas of haemorrhage and necrosis. One artery showed necrosis of all coats and scanty cellular infiltration with polymorphs, lymphocytes, plasma cells, and reticulo-endothelial cells, together with surrounding fibrosis. Several blocks from the kidneys showed a number of small arteries with areas of medial fibrosis. No fungal mycelium was seen in the sections from the pancreas or kidney.

Bacteriology.—Material from the lung cavity showed conidia typical of the *Aspergillus* genus. Cultures yielded a heavy growth of *Aspergillus fumigatus* Fresenius, together with a scanty growth of *C. albicans*, coagulase-negative staphylococci, and haemolytic streptococci, not of Lancefield groups A, C, or G.

In view of these findings the cause of death was considered to be toxæmia due to post-influenzal bronchopneumonia complicated latterly by aspergillus infection. Neither the purpura nor the presence of *C. albicans* seemed to contribute significantly.

Discussion

The occurrence of primary aspergillus infection of the lungs is well recognized, particularly in France and America. It occurs most often in patients who are in contact with fungus-contaminated grain, such as agricultural workers and pigeon-feeders. The clinical manifestations of this disease may briefly be said to fall into three groups: the bronchitic, the acute bronchopneumonic, and the chronic granulomatous types, the latter simulating tuberculosis (Virchow, 1856; Renon, 1897; Van Orstrand, 1940; Cooper, 1946).

Secondary infection associated with other lung diseases is also described, and may occur in tuberculous cavities, bronchiectasis, and even bronchogenic carcinoma (Lapham, 1926; Kampmeier and Black, 1934; Donaldson *et al.*, 1942). Sometimes a blood-borne dissemination gives rise to endocarditis, granulomatous lesions in many organs, meningitis, and even brain abscess (Geiger *et al.*, 1945; Cawley, 1947; Grekin *et al.*, 1950).

The interest of our patient lies in the rapid development of a cavitating bronchopneumonia while massive doses of antibiotics were being administered. The extent of the lung disease shown radiologically was greater than expected from the physical signs, but was in keeping with her progressively deteriorating condition. The necropsy findings confirmed the presence of bronchopneumonic consolidation and of cavitation in the left upper lobe, the wall of which was lined with mycelium. Mycelium was also found in other parts of the lung.

Recent reports have shown the frequent association of fungus infection with antibiotic therapy. Thus Woods *et al.* (1951) describe a series of 25 cases of moniliasis apparently a direct sequel of the use of antibiotics. Of these, 20 had oro-pharyngeal, 3 intestinal, and 2 broncho-pulmonary moniliasis. They suggest that suppression of bacteria usually competing for food with the coexisting *C. albicans* is probably the most important factor in the development of these infections. The disturbance of vitamin synthesis due to alteration of bacterial flora in the gastro-intestinal tract may also be of importance. Harris (1950) reports some success with vitamin-B complex in the prevention and treatment of moniliasis following antibiotic therapy. Foley and Winter (1949) suggest that penicillin may actually enhance the growth and pathogenicity of *Candida* species.

Tómaszewski (1951) recently analysed the side-effects of 126 cases treated with chloramphenicol and "aureomycin"; he remarks on the frequency of a fungal flora in the oral cavity, with a disappearance of the normal bacterial flora. Of particular relevance to our case is the report by Zimmer-

man (1950) of three cases of mycotic endocarditis, two of which were due to aspergillus infection, following antibiotic therapy.

We would suggest that in this case, also, the use of penicillin and chloramphenicol predisposed the damaged lung to infection with *Aspergillus fumigatus*, and that the terminal condition was due to the fungus rather than to any pathogenic bacteria. The case has been presented, therefore, to illustrate one of the dangers of antibiotic therapy—a subject of considerable interest at the present time. With the increasing use of antibiotics, similar cases may be seen more often in the future.

Summary

A middle-aged woman was treated with penicillin, streptomycin, and chloramphenicol for post-influenzal bronchopneumonia. At post-mortem examination the presence of *Aspergillus fumigatus* infection of the lungs was discovered. The relation of the infection to antibiotic therapy is discussed.

We are indebted to Dr. R. S. Bruce Pearson, Professor H. A. Magnus, and Dr. A. C. Cunliffe for advice in the preparation of this paper; and to Major H. A. Dade, of the Commonwealth Mycological Institute, Kew, for confirming the species of *Aspergillus* isolated.

PERIPHERAL NEURITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS

BY

R. H. HEPTINSTALL, M.D.

Senior Lecturer in Pathology

AND

G. S. C. SOWRY, M.D., M.R.C.P.

Assistant to the Medical Unit

St. Mary's Hospital, London, W.2

Peripheral neuritis has not been described as a feature of systemic lupus erythematosus, although it is well known in the closely related condition of polyarteritis nodosa.

The course of systemic lupus erythematosus has been fully described by many authors, notably Libman and Sacks (1924), Keil (1933), Baehr, Klemperer, and Schiffrin (1935), Klemperer, Pollack, and Baehr (1941), and Cluxton and Krause (1943), but none of these makes reference to peripheral neuritis, nor do the case reports of Kaposi (1872), Goeckerman (1923), Keefer and Felty (1924), Jarcho (1936), Fergusson, Milne, and Shand (1949), Beare (1949), or Gold (1951). Ginzier and Fox (1940) report bilateral wrist-drop in their patient twenty-four hours before death, but without investigation into its cause, clinical or pathological.

No mention of systemic lupus erythematosus is made by Richards (1951) in a comprehensive review of ischaemic lesions of peripheral nerves.

The following case is therefore put on record.

Case Report

A housewife aged 34 was originally admitted to the Maida Vale Hospital for Nervous Diseases on June 23, 1949, with a five-weeks history of weakness of the legs and paraesthesiae in her hands and feet. In March she had had a febrile illness, associated with a rash, mainly on the face, that had been diagnosed as rubella. A right-sided pleurisy in 1947 was the only past medical history of note, and she had no recollection of having taken any drugs. There was no significant family history of illness.

Examination revealed a persistent pyrexia of 102 to 103° F. (38.9 to 39.4° C.), with a tachycardia of 100 to 120 a minute associated with marked malaise and wasting. An erythematous maculo-papular eruption was seen on the cheeks, bridge of the nose, angles of the jaw, and wrists. The mucous membranes were generally pale, but there was inflammation of the mouth, tongue, and pharynx. The lymph nodes were not enlarged and neither the liver nor the spleen was palpable. No abnormality was found in the respiratory system, abdomen, or cardiovascular system, and the blood pressure was 135/85 mm. Hg.

In the nervous system, the upper limbs showed a bilateral motor weakness, most marked peripherally, and all the tendon reflexes were absent. Sensation was normal apart from slight loss of two-point discrimination in each hand. A generalized flaccid weakness of the lower limbs was again most noticeable in the periphery, knee-jerk and ankle-jerks were absent, and there was a bilateral flexor plantar response. Light-touch sensation was absent in both legs up to the knees, and vibration sense, while impaired up to the knee on the right side, was completely absent on the left. Pin-prick sensation was unaffected. Calf tenderness was marked in both legs.

The urine showed a heavy cloud of albumin, a large number of erythrocytes, and a few pus cells but no casts. Numerous investigations were negative, including agglutination reactions, the blood W.R. and Kahn test, and an x-ray film of the chest. A blood examination revealed: haemoglobin, 73% (Haldane) (10.8 g. per 100 ml.); red cells, 4,300,000 per c.mm.; white cells, 4,420 per c.mm. (neutrophil polymorphs 2,800, eosinophils 360, lymphocytes 1,260 per c.mm.). Lumbar puncture showed a pressure of 170 mm., with no block, 120 mg. of protein and 695 mg. of chlorides per 100 ml., and 5 lymphocytes per c.mm.

Owing to the development of occasional pulmonary crepitations, a course of penicillin and "sulphatriad" was given, but there was no clinical improvement. Vitamin B was administered by injection and later by mouth with nicotinamide and ascorbic acid, but, beyond relieving the stomatitis to some extent, did not appear to have any effect.

Blood culture was negative on admission, but on three subsequent occasions *Bact. faecalis alkaligenes* was grown, sensitive to streptomycin *in vitro*. A week's treatment with this antibiotic (0.5 g. six-hourly) and a further course in August brought no improvement.

A slight generalized lymph-node enlargement developed at this time, but the spleen remained impalpable throughout. Lymph-node biopsy from the left axilla and a sternal marrow examination by direct smear showed no significant abnormality.

Anaemia and leucopenia developed slowly, and by July 27 the haemoglobin was 45% (Haldane) (6.6 g. per 100 ml.), and there were 2,400 white cells per c.mm. (neutrophil polymorphs 1,600, lymphocytes 600, monocytes 200 per c.mm.). On this day 3 pints (1.7 litres) of Group A Rh-negative blood was given, raising the haemoglobin to 70% and improving the general condition, but not reducing the temperature.

By now some improvement in the peripheral neuritis was apparent, although the tendon reflexes were still absent and

the wasting was no less obvious. A further blood transfusion of 3 pints (1.7 litres) was given on August 19, when the haemoglobin had fallen to 60%.

On the following day five epileptiform seizures occurred with loss of consciousness and movements of the head and eyes to the left. For the remainder of the illness bilateral extensor plantar responses were present and bilateral retinal exudates were also noted. Lumbar puncture on August 22 showed 90 mg. of protein per 100 ml. and 12 lymphocytes per c.mm.

The skin lesions had gradually disappeared and by August 25 there was only a slight scaling in the affected areas. The blood pressure now was 120/90 and the urine showed a heavy precipitate of albumin. The heart was not enlarged and there were no significant murmurs and no pericardial rub. Her general condition remained grave, with a pyrexia of 100 to 102° F. (37.8 to 38.9° C.) and a tachycardia of 110 to 130 a minute. On August 25 she was transferred to St. Mary's Hospital.

The relevant investigations thereafter included: Plasma proteins 4.8 g. per 100 ml. (albumin 2.1 g., globulin 2.7 g.); E.C.G., low voltage in all leads with flat or absent T waves. Muscle biopsy showed no evidence of polyarteritis nodosa.

A course of chloramphenicol was given (0.25 g. six-hourly for six days), and a further course of penicillin (500,000 units twice daily), but with no effect. Late in November the temperature fell to normal, but the tachycardia persisted and her general condition deteriorated. Oedema developed, with a large ascites and a right pleural effusion, and the blood pressure rose steadily to 170/120. Severe abdominal pain occurred on December 16, and on the 18th there was evidence of acute generalized peritonitis. A laparotomy was undertaken, but the patient died on December 18 while on the operating table.

Necropsy Report

Necropsy was performed on December 19. *Cardiovascular system*: The visceral pericardium had a patchy gelatinous appearance and the myocardium was pale brown in colour with scattered paler areas throughout its substance. The endocardium, valves, and coronary arteries appeared normal. The heart weighed 375 g. *Respiratory system*: There was a small right hydrothorax and both lungs were very oedematous. *Digestive system*: The peritoneal cavity contained a large amount of turbid fluid. *Haemopoietic system*: The spleen was of normal size, firm, and congested, and had a small infarct. The Malpighian bodies and trabeculae were prominent. *Genito-urinary system*: The kidneys, each weighing 220 g., were pale in colour, and prominent glomeruli and small scattered haemorrhages were visible in the cortex, which was of normal width. *Nervous system*: No macroscopic changes were noted.

Microscopical Examination

Cardiovascular System.—The pericardium was thickened and showed a diffuse cellular infiltration, the main components of which were lymphocytes and plasma cells. Organization was occurring and capillary loops and fibroblasts were conspicuous. In the adipose layer of the epicardium there were granular eosinophilic areas, probably representing changes in the ground substance. The myocardium showed scattered areas where muscle fibres had disappeared. There were no distinctive connective-tissue changes. The endocardium and valves showed no abnormalities.

Respiratory System.—There was a generalized oedema, but neither vascular nor connective-tissue changes were observed.

Digestive System.—The small intestine showed several small vessels with eccentric intimal thickening; similar changes were seen in the mesenteric vessels.

Haemopoietic System.—The spleen showed the typical concentric periarterial fibrosis found in systemic lupus erythematosus (Fig. 1).

Genito-urinary System.—In the kidneys, the glomeruli showed both "wire loop" lesions and patchy necrotic areas, often associated with crescents. The interstitial tissue was diffusely infiltrated with lymphocytes and plasma cells. Fibrinoid necrosis was present in afferent arterioles and interlobular arteries. Cellular reaction in relation to these was minimal.

Central Nervous System.—No vascular changes were found in the brain, although numerous sections were examined.

Examination of peripheral nerves in the leg showed that some fibres had disappeared but most of them remained, showing no abnormality with a myelin stain. The endoneurium was increased in amount, varying from bundle to bundle. Abnormalities of the blood vessels in the epineurium were noticed. There were no active lesions such as were seen in the kidney, but numerous vessels showed evidence of previous damage. The arteriole in Fig. 2 shows evidence of old obliteration of the lumen with recanalization, and in relation to it is a group of chronic inflammatory cells. The small artery seen in Fig. 3 shows an eccentric fibrotic thickening in the intimal zone with thinning of the muscular wall over it. The internal elastic lamina is intact and new elastic is present in the fibrous tissue. This vessel has been followed in serial sections, but there was no evidence of previous complete rupture of the wall with loss of elastica and fibrous replacement of the media such as one normally sees in healed periarteritis nodosa.

In discussing peripheral neuritis in polyarteritis nodosa, Kernohan and Woltman (1938) described healed vessels in which regeneration of the internal elastica had taken place, and the vessel in Fig. 3 may represent either an organized thrombus or a healed necrotizing lesion with regrowth of the internal elastica lamina. The distribution of the vascular lesions was patchy. Sections taken at certain levels showed completely normal vessels, while those taken at others showed lesions such as have been described.

FIG. 1.—Spleen. Concentric layers of collagen surrounding small artery. Haematoxylin and van Gieson. ($\times 110$.)

FIG. 2.—Peripheral nerve. Arteriole has been obliterated and recanalized. Chronic inflammatory cells in relation to it. Haematoxylin and eosin. ($\times 180$.)

Discussion

The combination of a prolonged pyrexial illness, renal dysfunction, serous effusions, and central nervous involvement of sudden onset suggested the diagnosis of either systemic lupus erythematosus or polyarteritis nodosa. The skin lesions and the progressive neutropenia were in favour

FIG. 3.—Peripheral nerve. Artery with gross intimal thickening and thinning of muscularis over it. New elastic-tissue formation. Hart-Sheridan method for elastic. ($\times 420$.)

of the former diagnosis, as was the female sex of the patient. On the other hand, the peripheral neuritis which gave rise to the presenting symptoms suggested polyarteritis nodosa, particularly when no previous account of this lesion in systemic lupus erythematosus could be found.

That this was a case of systemic lupus erythematosus could not be doubted after the post-mortem examination, although there is no satisfactory explanation for the repeatedly positive blood cultures.

The diagnosis of peripheral neuritis is established by the combination of a lower motor-neurone lesion, paraesthesiae, and sensory loss in all four limbs, together with bilateral calf tenderness.

From the histological evidence already given, it is postulated that the neuritis was of a similar nature to that described in polyarteritis nodosa by Wohlwill (1923), due to ischaemic changes in the nerves produced by an obliterative arteritis of the arteria nervorum. In view of the now generally accepted belief that systemic lupus erythematosus is a widespread disease of collagen it is not surprising to find these vessels involved. Indeed, rather is it to be wondered why polyneuritis is not a more frequent manifestation of this disease process.

Summary

A case of systemic lupus erythematosus in a woman aged 34 is described in which the presenting picture was one of peripheral neuritis.

It is considered that the peripheral neuritis was due to ischaemia consequent on vascular lesions in the vessels supplying the nerves.

We wish to record our indebtedness to Dr. J. W. Litchfield and Dr. P. H. Sandifer, the physicians in attendance on the patient, for their permission to report this case and for the interest they have shown in this paper; to Dr. J. F. Taylor, who carried out the necropsy; and to Mr. A. Beasley for the preparation of countless serial sections. We are most grateful to Professor W. D. Newcomb and Professor G. W. Pickering for their help and advice.

A FOLLOW-UP STUDY OF 238 LEUCOTOMIZED PATIENTS*

BY

HUNTER GILLIES, M.D., F.R.C.P.Ed., D.P.M.

BARBARA HICKSON, S.R.N., R.M.N., D.N.

AND

W. MAYER-GROSS, M.D., F.R.C.P.

(From the Department of Clinical Research, Crichton Royal, Dumfries)

This follow-up study was undertaken to assess the results of standard prefrontal leucotomy in 238 patients who underwent the operation at Crichton Royal between 1943 and 1948. Although it may be accepted that the value of the operation is established for chronic obsessional states and chronic affective psychoses, unexpected failures and unexpected successes are often met with. It was hoped that from a study of our own patients there would emerge criteria that would help us to select those individuals likely to respond to the operation. A special interest was taken in schizophrenics because they made up more than three-quarters of the series and because they form the great therapeutic problem. Partridge (1950) has published a valuable book on his personal follow-up of 300 patients over a period of one and a half to three years after operation; he was more interested in the clinical appearances than in the tabulation of results. We, on the other hand, to avoid being influenced by clinical impressionism have made a detailed examination of our material and results.

Material

TABLE I.—Composition of the Clinical Material

Diagnosis	No. of Cases	Percentage of Cases
Schizophrenia	194	81.1
Affective psychoses	21	8.9
Obsessional neurosis	14	6.3
Mainly organic psychoses	9	3.7
Total ..	238	100

Important features of our series were that all the patients were diagnosed and selected for operation according to the uniform standards of our hospital, while with the exception of the first 16 patients all operations were carried out by the same surgeon. The diagnosis in the 238 cases is shown in Table I. Most of the patients received the standard coronal cut of Freeman and Watts, but in 52 chronic cases

*Paper read to the 110th Annual Meeting of the Royal Medico-Psychological Association at Crichton Royal, Dumfries, on July 12, 1951.

the incision was varied so as to isolate the orbital lobes and to spare the upper quadrants; this modification was abandoned because the results were less good (Egan, 1949).

The mortality rate from the operation in our series was 3%. There were none of the "delayed post-operative deaths" described by Meyer and McLardy (1948). The incidence of post-operative epilepsy, including single fits, was 8%, most of these being male catatonic schizophrenics. There were no other serious organic complications, and persistent enuresis was not encountered.

Selection of Patients.—Our criteria of selection have always been conservative, so that only 13 of our patients had been ill for less than two years. The operation is not considered until full courses, often repeated courses, of the appropriate physical treatments have failed to induce a sustained remission. Each case was discussed pre-operatively at a staff conference, and if we thought there was any reasonable hope of remission without operation then leucotomy was avoided. Our criteria for selection included a good pre-psychotic personality, good retention of personality, and the presence of emotional tension.

Method of Follow-up

The method of follow-up we adopted for discharged patients was by personal letter to informants whom we knew to be reliable. These informants were either the relatives, the family physician, a psychiatric social worker, or, in the case of hospital patients, the appropriate medical superintendent. In some cases we also wrote to the patient himself. Our letter put the following specific questions: (1) Is the patient fully and satisfactorily occupied? (2) Is he happy and his old self again? (3) Is he easy to get on with and does he take part in social life? (4) Are there any special difficulties? (5) Do you find him a different person from what he was before his illness began?

The first inquiry elicited satisfactory information in a great majority of cases, and at the end of our investigation only one of the 238 patients was untraced. A postal follow-up has disadvantages; so has a personal interview, because the patient can give a deceptive impression of normality, and this has to be corrected by more objective opinions from relatives and doctors. We are satisfied that our study gives an accurate picture of the leucotomized patient's place in society, and, after all, criteria of success or failure after leucotomy are mainly social criteria. It was found that the patients' own letters reflected an uncritical self-satisfaction and lack of judgment, while they were prone to describe ease of social relations when in fact their social adaptation was impaired.

The average time between operation and our inquiry was four and a half years; the shortest was one year four months and the longest seven years two months. There is no doubt that follow-up studies made less than one year after operation give a deceptive picture of the results of leucotomy.

Results

The patients' condition during the first four months of 1950 is indicated in Table II. From this we see that, broadly speaking, of these prognostically hopeless cases almost one-third are living a normal or almost normal family life, and more than one-fourth are usefully and gainfully employed. Of those who remained in hospital almost half are much improved; they are happier and are easier to nurse. Our findings over a lengthy period confirm, therefore, the findings of those workers who have followed their cases for only a short time.

Apart from assessment of the therapeutic results of the operation, an attempt was made to discover which factors influenced these results.

Factors Influencing Results

Sex.—Although, like other workers, we have found a greater number of good results in females, our figures are not significant. However in schizophrenia this same trend

TABLE II.—Graded Condition of Patients at Time of Investigation

Grade	Condition	Definition	No.	%
I	Recovery	Social life as before illness. Working at old job or at one at the same occupational level as before illness. Minimum of any form of symptoms	41	17.2
II	Social recovery	Relatively normal social life. Lower standard of work; may or may not be gainfully employed. Some symptoms of psychosis or marked post-leucotomy symptoms present	31	13.0
III	Social defect	Deterioration in social behaviour, sometimes even antisocial. May or may not be gainfully employed. Symptoms as with social recovery	15	6.3
IV	Home invalid	Require care and observation in their daily life, and in any simple occupation which they may do at home. Not otherwise employed. Marked symptoms still present	15	6.3
Va	Hospital invalid	Generally improved—i.e., able to work in hospital and take part in entertainments. Have some form of parole	21	8.8
Vb	Hospital invalid	Easier nursing problems; no longer so aggressive and impulsive. Some may have a simple occupation in the ward	20	8.4
Vc	Hospital invalid	No change since operation	22	9.3
Vd	Hospital invalid	Deteriorated	28	11.8
VR	Readmitted to hospital, and in at April, 1950		35	14.7
VI	Dead	As a result of operation From other causes	7	3.0
			2	0.8
VII	Untraced		1	0.4
Totals			238	100

has been found by others in spontaneous remissions (Guttman, Mayer-Gross, and Slater, 1939) and also in those who received insulin coma treatment (Mayer-Gross, 1951, unpublished observations). It may in part be correlated with the greater ease with which a female can be again accepted into family life.

Age at Operation.—Good results occurred equally in our three age groups: (a) those under 30 years; (b) those of 30–39; and (c) those of 40 and over. However, the oldest age group had the smallest number of relapses.

Pre-morbid Personality.—By examining the case records and social histories we classified our patients into those who had been well adapted to life and society before the psychosis appeared and those whose pre-morbid adaptation had been poor and unstable. Of those who had a well-adapted pre-morbid personality 68% made grade I or grade II recoveries. Of those who were poorly adapted before their illness only 35% made grade I or II recoveries.

Time Spent in Hospital.—By this we mean the total of time in hospital since the illness began. Our total of grade I and II recoveries was 50% of those who had been in hospital under one year and only 11.5% of those who had been in hospital more than five years.

Duration of Illness.—By this we mean the total time since symptoms first became apparent. Here our findings were unexpected and we think important. In the group of patients who had been ill for 10 years and over there were almost as many grade I and II recoveries as there were in the group who had been ill less than five years (see Table III).

TABLE III.—Relationship Between Duration of Illness and Condition at Time of Investigation

Duration of Illness (years)	Grade (see Table II)										Totals
	I	II	III	IV	Va	Vb	Vc & Vd	VR	VI	VII	
Under 5	14	11	2	6	6	4	12	18	3	1	77
5–9	14	9	8	3	6	7	15	11	3	0	76
10 and over	13	11	5	6	9	9	23	6	3	0	85
Totals	41	31	15	15	21	20	50	35	9	1	238

The conclusion is that, by itself, long duration of illness should not weigh against performance of the operation. Freeman and Watts (1950) make this same point. The apparent discrepancy between the effects of length of illness and length of stay in hospital is probably to be explained by the view that the patient who is able to remain outside hospital, even though ill, does so because of his good retention of personality and his social adaptability.

Retention of Personality.—By this we understand that, despite his psychosis, the patient retains an interest in his appearance, in personal and topical affairs, and in social intercourse. Of those patients with good pre-operative retention of personality 46% made grade I or II recoveries. Of those who seemed deteriorated before operation 21%, less than half, made grade I or II recoveries. Even this 21% is quite a respectable figure, but then it is notoriously difficult, especially in schizophrenia, to determine the presence or absence of deterioration. We found that probably the best test is the response to electric convulsion treatment (E.C.T.), and we would now hesitate to stigmatize a patient as too deteriorated for operation until we had seen the response he made to a course of electroplexy.

Response to Electric Convulsion Therapy.—Of those who had made a good, albeit transient, response to E.C.T. given before leucotomy 22% made grade I recoveries, while of those who had shown no response to E.C.T. only 3.5% made grade I recoveries. Table IV illustrates these results.

TABLE IV.—*Relationship Between Response to E.C.T. and Condition at Time of Investigation*

Clinical Response to E.C.T.	Grade (see Table II)										Totals
	I	II	III	IV	Va	Vb	Vc & Vd	VR	VI	VII	
No improvement	2	11	6	2	5	5	16	8	2	0	57
Temporary improvement	33	19	8	13	13	13	23	22	6	1	151
No E.C.T. given	6	1	1	0	3	2	11	5	1	0	30
Totals ..	41	31	15	15	21	20	50	35	9	1	238

Response to Insulin Coma Therapy.—On the other hand, we found no significant differences after leucotomy between those schizophrenics who had made some response and those who had made no response to insulin coma therapy.

Emotional Tension.—It is generally agreed that the best results of leucotomy occur in those patients who still show a strong affective reaction to their psychosis. As the presence of this affective reaction or emotional tension was one of our main criteria of selection, there were only 16 patients in the series who showed no obvious tension: the figures are therefore too small for comparison. It is interesting, however, that even of these 16 patients five made grade I or II recoveries.

Diagnostic Categories.—The series included 35 cases of affective psychosis and obsessional neurosis and 194 cases of schizophrenia. In the former group 60% made grade I or II recoveries, while only 27% of the schizophrenics reached these grades. Surprisingly, all our five cases of mania made grade I or II recoveries.

Relapses.—It was found that of 115 patients who had improved enough to be discharged from hospital 22 relapsed after an average period of two and a quarter years free from symptoms. When this group of relapsed cases was compared with those who had maintained their recoveries the only significant factor found was that the pre-operative personality was more often intact in the recovered cases than in the relapses (Gillies and Mayer-Gross, 1950).

Summary and Conclusions

A follow-up study was made of 238 chronic psychiatric patients who had undergone the standard leucotomy operation some one to seven years previously. The best results occurred in those whose pre-operative personality

was more or less intact, who had well-adapted pre-psychotic personalities, and who had been only a short time in hospital. If these factors were present, long duration of illness did not worsen the prognosis.

In schizophrenia the best test for pre-operative deterioration is afforded by the response to electric convulsion treatment.

Of the psychiatric patients who have hitherto been regarded as hopeless hospital invalids the standard leucotomy can return one-third to a normal or almost normal social life and can fit one-quarter for gainful employment.

Broadly speaking, the prognostic criteria for leucotomy are still those well-tried criteria that hold for the untreated psychosis.

We are indebted to Dr. P. K. McCowan for his advice and for permission to publish the material; our thanks are also due to Mr. R. L. Beveridge, who operated on most of our patients.

FAMILIAL ERYTHEMA NODOSUM

BY

JOHN FRY, M.B., F.R.C.S.

(From a General Practice)

Erythema nodosum is a clinical entity with a characteristic skin eruption, usually accompanied by a general constitutional upset. Diagnosis of the eruption is easy, but there is still some uncertainty with regard to the aetiological aspects of this condition. The general consensus of opinion is that it is a non-specific reaction in a sensitive subject in response to a number of various allergens. These are best discussed under separate headings.

Tuberculosis.—It is probable that erythema nodosum is most often associated with the primary tuberculous complex, particularly in children and adolescents. In these cases the eruption occurs when the patient first develops hypersensitivity to tuberculin. The time-interval for this to happen has been estimated at three to eight weeks from the time of infection. The frequency with which erythema nodosum is associated with primary tuberculosis apparently varies individually and also nationally. Thus Wallgren (1938) estimated that 30% of primary infections in Scandinavia were associated with the eruption; Dunlevy (1949), in Eire, found only a 2.8% incidence. In Scandinavia the average age of primary infection is much higher than that in Eire. Wallgren, in a series of 800 cases, reported that 95% had a positive tuberculin skin reaction. This is significant, because these Scandinavian children could normally have been expected to have a negative reaction. He also describes a number of cases in which the change of the skin response from negative to positive was definitely associated with the eruption.

Punch (1941) was able to show that in student nurses the change from a tuberculin-negative to a tuberculin-positive skin reaction was often accompanied by an eruption of erythema nodosum. Bruce Perry (1944), in a series of 112 cases, found a positive Mantoux reaction in 54%. In those under 15 the incidence was 75% and in those over 15 it

was only 25%. Doxiadis (1949) found 88% tuberculin-positives out of 100 children under 15 who developed erythema nodosum. There are relatively few reports on series of adult cases. Löfgren (1946) considers that a non-tuberculous cause is more frequent in adults.

Acute Rheumatism.—The usual view held in this country, until recently, was that erythema nodosum was a frequent accompaniment of acute rheumatism. All the latest papers discussing the aetiology of erythema nodosum stress the rarity of this association (Wallgren, 1938; Bruce Perry, 1944; Löfgren, 1946; Doxiadis, 1949). The points against the rheumatic theory are the absence of any signs of carditis in erythema nodosum, the different sex and age incidence, and the lack of response to salicylates. Although rheumatic fever as a common cause is discredited, it is certain that erythema nodosum may occasionally be a manifestation of acute rheumatism.

Streptococcal Infection.—It was Collis (1932) who first drew attention to the fact that tuberculin-negative cases of erythema nodosum had a markedly higher sensitivity to streptococcal nucleoprotein at the time of the eruption. It seems probable that erythema nodosum may be an expression of streptococcal allergy in certain cases. It is from this cause that cases of recurrent attacks occur. Rotnes (1936) reported a case in which there had been 14 attacks, usually after a pharyngitis or tonsillitis.

Sarcoidosis.—Erythema nodosum is occasionally met with as a sign of sarcoidosis (Kerley, 1942, 1943; Löfgren, 1946; Crawley, 1950).

Sulphonamide Hypersensitivity.—In the early days of sulphonamide therapy skin rashes of diverse types were common. At the present time, with compounds of lower toxicity, these rashes are much less frequent. Occasionally an eruption indistinguishable from erythema nodosum is found in these circumstances, and it disappears rapidly when the drug is stopped. It is difficult to know whether the eruption is the result of the primary condition or whether it is a complication of the treatment.

Coccidioidomycosis.—For many years a chronic granulomatous condition, due to infection by *Coccidioides immitis*, has been prevalent in the San Joaquin Valley in California. This condition has a number of features akin to tuberculosis. There is a mild primary stage of infection which is sometimes followed by a general blood-stream spread and a possible late occurrence of chronic granulomata in the lungs and other organs. About 5% of these cases have a typical eruption of erythema nodosum associated with the primary stage of infection.

Miscellaneous.—There are a number of other conditions with which erythema nodosum has been associated—for example, meningococcal, gonococcal, and staphylococcal septicaemias; lymphogranuloma inguinale; syphilis; lymphadenoma; and intoxication with bromides and iodides.

Question of Specificity.—The recognition of small epidemics of erythema nodosum gave rise to the theory that it is a specific disease (J. O. Symes, 1921; Lendon, 1925). The causal organism has, however, never been convincingly isolated. Further studies of these epidemics suggested that in the majority there was evidence of a recent simultaneous contact with the tubercle bacillus.

Three cases of erythema nodosum which occurred simultaneously in one family are described.

Case Reports

The family, in October, 1950, comprised the parents and three young children: Mary aged 7½, Janet 5, and Roger 3½. They lived in a house of three bedrooms on the outskirts of South-east London. The parents slept in one bedroom, the two girls shared a double bed in the second, and Roger had a small room to himself. The father, a builder's decorator aged 30, had been unwell for some weeks with a cough, and on October 21 bilateral open pulmonary tuberculosis was diagnosed. He was at once

ordered to bed. The mother then slept with her two daughters in their double bed, and the father had a separate room. He remained there until November 29, when he was admitted to a sanatorium. When tuberculosis was diagnosed the rest of the family were investigated at the local chest clinic. Chest radiographs showed no signs of any disease, and tuberculin tests on the children were all negative.

On December 1 the mother was seen on account of a sore throat, of three days' duration, and a painful eruption on her legs, which she had noticed for 12 hours. She was a healthy young woman of 28. She had a clean medical record, and was at this time four months pregnant. There were no cough, joint pains, or any digestive upset. The whole family had had a meal of prawns on the previous day. Examination at this stage revealed a normal temperature—98.2° F. (36.8° C.)—and pulse rate 81. The fauces were hyperaemic, but there was no exudate. On the extensor aspects of both legs there were about a dozen typical areas of erythema nodosum. Over the next four days her general condition became a little worse, with a fever up to 100° F. (37.8° C.), and increasing pain in the legs. On the fifth day she began to improve, and the eruption had disappeared by the tenth day. She received no specific treatment.

On December 1 Mary, aged 7½, began to feel unwell with vague dull mid-abdominal pain and fever—99.5° F. (37.5° C.)—and a pulse rate of 92. She showed no abnormal physical signs at this stage. There was no sore throat, no vomiting or diarrhoea, or any joint pains. On December 4 the characteristic eruption of erythema nodosum appeared on the anterior aspects of both legs. By this time she felt better and there was no abdominal pain or other constitutional upset. The eruption persisted for eight days. She, too, had no specific therapy.

Janet, aged 5, was quite well in spite of the appearance of typical areas of erythema nodosum on her legs on December 6. There was no fever or tachycardia. Her eruption had disappeared within seven days.

Roger, aged 3½, had during all this time remained in his usual good health and continued to do so.

All four were further investigated. Chest radiographs of the mother, Mary, and Roger on December 21 were considered to be within normal limits. Janet's radiograph showed a slight degree of left hilar enlargement. Further radiographs on June 4, 1951, were all regarded as within normal limits. A tuberculin patch test was performed on all four on December 15, and Janet showed a positive response. A Mantoux, 1/1,000, however, resulted in a positive reaction in the other three. The family has remained well since December, 1950, until the time of writing (July, 1951). The mother was delivered of a normal healthy boy in April, 1951; he is Mantoux-negative (1/1,000), and is about to have B.C.G. vaccinations. Janet and Roger had measles in March, but have otherwise remained well. The father is still in a sanatorium, but is due for discharge soon.

Discussion

It seems certain that in the two girls the development of a positive tuberculin skin reaction accompanying a primary tuberculous infection was associated with an eruption of erythema nodosum. This is also likely to be the case in the mother, but it is inconclusive, as a previous skin test was not done.

A number of previous reports describe similar series of cases. The most remarkable of these was an "epidemic" which occurred in the Welsh town of Mynyddislwyn in the summer of 1920. It is reported by J. O. Symes (1921), quoting R. E. Roberts, who was then the local M.O.H. Over a period of five weeks 50 cases of erythema nodosum were seen in an area enclosing three streets. There had been no cases in this town for the previous 15 years. There is no mention of any search for a tuberculous cause. W. L. Symes (1907) reported 12 cases occurring over a period of four weeks in a girls' residential school of 100 pupils.

Robinson (1926) described three cases. Lendon (1925), in a survey, quoted 10 instances of outbreaks of erythema nodosum; in two of these there was a subsequent tuberculous infection. Demole (1933) reported three cases in a dressmaking school where a tuberculous source was found. He also states that in the nineteenth century there were widespread epidemics of erythema nodosum in Bosnia, Jutland, and Turkey.

Wallgren investigated an outbreak which occurred in a class of 34 girls: 18 suffered simultaneously from a febrile condition. On follow-up 12 of these subsequently developed erythema nodosum within 6 to 10 weeks. Three months previously there had been an open case of pulmonary tuberculosis in the class. Further small series with a tuberculous aetiology are reported by Lannois (1892), Ledoux (1932), Parisot and Saleur (1933), Bertoye and Bernheim (1935), and Mouriquand and Weill (1937). Cibils Aguirre (1933) has collected a number of series of "familial erythema nodosum" cases with a probable tuberculous cause.

It seems likely that most of these multiple cases of erythema nodosum have been associated with a primary tuberculous infection. It is true that a definite tuberculous contact has not been found in some of these, but perhaps the contact was of a transient and elusive nature.

Summary

The possible aetiology of erythema nodosum is discussed. It is a non-specific reaction to a variety of allergens. The most important of these is the association of erythema nodosum with a primary tuberculous infection.

A report is given of three cases occurring simultaneously in one family. In these there was a definite tuberculous cause.

Previous reports of similar cases are reviewed.

According to the Hungarian News and Information Service the first Congress of the Hungarian Microbiological Society was held in Budapest during January, and was attended by 250 Hungarian scientists, and 26 scientists from eight other countries, including the Soviet Union, China, and Korea. Eighteen lectures were delivered to plenary sessions of the Congress, and nearly 150 to meetings of its eight sections. The society was formed during 1951, and the congress was the first public presentation of the work of Hungarian microbiologists. Dr. Károly Rauss is engaged on research into a preventive vaccine for dysentery. Professor Rezső Manninger is working on vaccines against fowl pest, swine fever, and other animal diseases. Typhoid fever carriers, antibiotics, and the manufacture of penicillin are all being investigated. The Parasite Section of the National Institute of Public Health is working on the prophylaxis of malaria. Messrs. Kardos, Kiss-Bagoly, and Deutsch discussed the question of the formation of bacteria from non-cellular protein.

A NEGATIVE BENZODIOXANE TEST IN PRESENCE OF A PHEOCHROMOCYTOMA

BY

HAROLD P. TULLOH, M.B., B.S.

House-physician, Derbyshire Royal Infirmary

Four cases of pheochromocytoma have been reported which gave a negative response to the benzodioxane (piperoxane) test before operation. Prunty *et al.* (1950) described the case of a man, under the care of Professor Pickering, in whom a large pheochromocytoma was removed at operation, despite a pre-operative negative benzodioxane test. Smithwick's case, described by Goldenberg and Aranow (1950), was that of a middle-aged woman with persistent hypertension and a negative benzodioxane reaction who was found to have a large pheochromocytoma at operation. Calkins and Howard (quoted by Goldenberg and Aranow) described a similar case. Beyer *et al.* (1951) reported a negative benzodioxane test in a woman aged 40 in whom a pheochromocytoma of the left adrenal was removed at operation.

The following case report concerns a woman with sustained hypertension and a negative benzodioxane reaction, who at necropsy was found to have a pheochromocytoma.

Case Report

A woman aged 25 was admitted in September, 1950, for gynaecological investigation following a prolonged history of menstrual disturbances, anorexia, and loss of weight, with associated attacks of blurred vision and frequent night sweats. Routine examination revealed a sustained hypertension ranging from 240/130 to 220/120 and a persistent tachycardia (88–120), although she was a psychologically stable patient. She had a large hypertensive heart but no congestive lung changes. Retinoscopy revealed gross papilloedema with haemorrhages, exudates, and attenuated arteries.

Investigations.—Sodium amytal test (see Fig. 1). The benzodioxane test, carried out as described by Goldenberg, with a calculated dose of 17 mg., gave a negative result (Fig. 2). An electrocardiogram showed gross left ventricular stress. Renal function tests showed a normal blood urea; albumin, red cells, and granular casts in all urine specimens; and imperfect function. An intravenous pyelogram was normal.

FIG. 1.—Graph showing results of the sodium amytal test.

FIG. 2.—Graph of the benzodioxane hydrochloride test.

The patient was given a course of intramuscular hexamethonium bromide without result, and subsequently a bilateral lumbo-dorsal sympathectomy was carried out by Mr. J. R. Ratcliffe. No tumour was palpated at operation. A week after the second stage of the operation she developed total blindness, with gross retinal oedema, and her blood pressure remained persistently high. The blood urea never rose above 40 mg. per 100 ml. Death occurred five weeks after the operation. Necropsy, performed by Dr. Ian Mackenzie, showed a large hypertensive heart, with renal changes consistent with chronic nephritis. A large phaeochromocytoma of the right adrenal was found, hidden deep under the right lobe of the liver.

Discussion

The use of the benzodioxane test was first described by Goldenberg *et al.* (1947), who stated that if the hypertension is due to an adrenaline- and noradrenaline-producing tumour, a drop of 20–50 mm. in both systolic and diastolic pressures occurs within four minutes, with a return to normal in 15 minutes. The result in the above case was therefore taken to be negative.

Certain features of the case suggested the necessity for a benzodioxane test. There was no history of pregnancy toxæmia or chronic nephritis, though the latter is an admittedly difficult differential diagnosis in the presence of signs of renal disease. Malignant hypertension is uncommon at this age in the absence of these two causes. The attacks of nocturnal sweating, persistent hypertension, tachycardia, and gross retinal changes aroused suspicion of a phaeochromocytoma.

It is suggested by Beyer *et al.* that noradrenaline is the immediate precursor of adrenaline in the body, and that in phaeochromocytoma there is an impairment of the transmethylation reaction, so that, as other observers have found also, the content of noradrenaline in the tumours may be 50 to 90% of the total pressor substances. The greater the preponderance of noradrenaline the greater the probability of a negative benzodioxane reaction.

Several theories have been put forward by Goldenberg and Aranow to account for a negative benzodioxane test. They assume that a "secondary mechanism" is set in motion by the effect of persistently excessive amounts of adrenaline or noradrenaline in the blood, which fails to be affected by the adrenergic blocking action of benzodioxane. Alternatively, this "secondary mechanism" may represent the "vicious circle" of experimental hypertension, and the phase of sustained hypertension, as in the above patient, is not entirely due to circulating adrenaline and noradrenaline, but to another pressor substance not blocked by benzodioxane. Goldenberg and Aranow suggest that at the time of the test there may be a lack of these pressor substances in the circulation, or that the standard dose of benzodioxane is quantitatively inadequate to deal with the circulating amines.

In Smithwick's case, chemical assay of the tumour showed no abnormal pressor substance which would be resistant

to the effects of benzodioxane. These occasional negative responses to benzodioxane in the presence of a phaeochromocytoma should not diminish the use of the test at the bedside.

If the test is negative or doubtful it should be repeated, particularly when other investigations suggest a tumour. It is unfortunate that the most reliable test—that by the injection of histamine intravenously as suggested by Roth and Kvale (1945)—is too hazardous for routine use. Repeated straight radiographs of the abdomen are a valuable procedure in certain cases. The insufflation of perirenal air, while a satisfactory procedure in some cases, can be dangerous in other than expert hands.

Whether such a procedure in the above case would have shown up the tumour is doubtful because of its position deep under the right lobe of the liver. Urinary assays of adrenal medullary hormone derivatives, as introduced by Engle and von Euler (1950; see also von Euler, 1951), are not yet readily available for use in diagnosis, though, if confirmed, their methods will provide considerable diagnostic certainty.

When a lumbo-dorsal sympathectomy is being performed the kidneys and adrenals should be palpated for a tumour, though in my case no tumour was detected.

A diagnostic laparotomy may be necessary occasionally, but hyperadrenalism may develop when the tumours are palpated, with acute cardiac failure supervening on an already overstrained cardiovascular system for hyperadrenalism. Thus the tumour should be removed at the initial operation (Hubble, 1951).

Summary and Conclusion

A case of phaeochromocytoma is described in a young woman of 25, in which a negative result to the benzodioxane test was obtained. Four similar cases from the literature are briefly reviewed, and the possible reasons for failure of the test are discussed. If the test is doubtful or negative when a phaeochromocytoma is strongly suspected it should be repeated, and other diagnostic measures undertaken.

I am indebted to Dr. Douglas Hubble, physician, Derbyshire Royal Infirmary, for much helpful and constructive criticism in preparing this report. I would also like to thank Dr. Ian Mackenzie for his most valuable necropsy report.

Under Service conditions there is a demand by military patrols for a convenient method of sterilizing small quantities of water in individual water-bottles. During the 1939–45 war when necessary a white tablet of "halazone" (para-sulphon-dichloramido-benzoic acid) was placed in the water-bottle filled with water and shaken vigorously to form chloramine. After 30 minutes one blue tablet (coloured sodium thiosulphate) was added and the bottle again shaken to remove the taste of the halazone tablet. It was found that these tablets deteriorated in humid tropical climates, becoming adherent to one another, and producing only small amounts of chloramine. New tablets have been produced using chloramine B (sodium-chlorobenzene-sulphonic acid amide), which has stored well for over two years in various theatres overseas, though unfortunately the tablet becomes hard and takes a long time to dissolve. With the new tablet detasting will be unnecessary, and the contact time for sterilization will be reduced to 15 minutes.

Medical Memorandum

Parkinson's Syndrome following Severe Herpes Ophthalmicus

A number of papers have recently appeared in various journals on the complications of herpes zoster. These are lesions of motor neurones, myelitis and meningitis, and encephalitis. Alajouanine and Griffith (1931) record a case of a girl of 17 who developed typical signs of disseminated sclerosis two years after a "herpes myelitis." The following case of Parkinson's syndrome occurred after severe herpes ophthalmicus.

CASE REPORT

A flight lieutenant aged 48 had a healthy Service record of nearly 30 years, apart from gastric symptoms spread over a number of years. He first noticed slowness of movement and marked general tremor in January, 1949. There was no history of varicella, but he thought he had had measles and mumps. In 1941 he was bombed, and his hands and face were burnt; a duodenal ulcer developed about four weeks later. He had no residual effects. In May, 1947, he contracted severe left herpes ophthalmicus with corneal ulceration, from which he took a long time to recover. He had felt ill and thought he had been febrile. The left side of his face was "dead" for some months, and an operation had been performed on the left lower lid. There was no history of any illness like encephalitis lethargica. He was not vaccinated or immunized either before or after his attack of herpes.

In November, 1949, he gave the typical picture of Parkinson's syndrome—mask-like facies, slow movement, festinant gait, tremor of both hands, stiffness of face and neck muscles, and slow speech. Rigidity of arms and legs with increased tendon-jerks was present. Examination of the central nervous system, chest, and abdomen showed nothing abnormal.

Investigations.—A radiograph of the skull and lumbar puncture were normal, and the Wassermann reaction was negative. Psychometric tests showed signs of cortical atrophy due to arteriosclerosis. His blood pressure was 138/86. His urine was normal.

The patient had had belladonna and hyoscine hydrobromide and then was given "artane" (trihexyphenidyl), 15 mg. daily at first, finally increased to 17 mg. daily. Relief of depression was the first symptom alleviated, then diminution of sialorrhoea; tremor was not so pronounced, but spasticity was not greatly relieved. He was to have had other drugs, when he was found dead in bed on September 14, 1950.

At necropsy no definite lesion was found that could account for death. His coronary and cerebral vessels showed no evidence of arteriosclerosis, but were in a state compatible with that of any other man of his age. Analysis of organs was negative. Death was recorded as cardiac failure due to Parkinson's syndrome. Sections of the brain stem and basal ganglia were not helpful.

COMMENT

There appeared to be three possibilities: (1) That herpes ophthalmicus was in no way connected with the subsequent lesion. (2) That herpes ophthalmicus was a precipitating factor. (3) That the subsequent lesion or lesions were due absolutely to the effects of the virus. Obviously, the second and third possibilities must be examined before accepting or rejecting the first. There was no history of any condition following the herpes ophthalmicus which would suggest a zoster encephalitis or encephalitis lethargica. The virus

responsible for herpes belongs to the group which produce degenerative changes in the nerve cells, and has also been termed the sensory analogue of anterior poliomyelitis. In the latter, encephalitis, myelitis, and brain-stem lesions may occur; in the former, encephalitis and cord lesions have occurred; brain-stem lesions are therefore within the realms of possibility.

Instead of regarding the virus as acting locally Head and Campbell (1900) put forward the view that the initial febrile phase indicated a general systemic infection; the evidence now accumulating suggests that there is a stage in which the virus is disseminated throughout the nervous system. Magnusson and Wohlfart (1942), on anatomical examination in a case of herpes zoster ophthalmicus, found slight general meningitis and herpetic changes in the Gasserian ganglion on both sides, though they were most pronounced on the side of the vesicles. Lhermitte and his colleague have shown that even in uncomplicated cases herpes zoster produces lesions in the posterior root ganglia and also causes inflammation of the anterior horns of the segments of the cord relative to the affected ganglia. Again, Lhermitte and Vermès (1930) describe lesions in the brain stem and basal ganglia which they found themselves and which were due to the virus of herpes zoster. In these the vessels are tortuous and distended with blood, there are scattered haemorrhages which, though small, are numerous, and areas that appear translucent on section owing to the presence of lacunae, particularly in the region of the pyramidal tracts. Although the patients were advanced in age the authors consider that the lesions are directly due to the herpes virus, since they are similar in type to lesions in the cord, and do not resemble lesions due to arteriosclerosis or thrombosis.

Gordon and Tucker (1945) mention a case in which a right hemiplegia with an aphasia developed three weeks after herpes of the ophthalmic division of the trigeminal nerve. The patient, aged 26, had no evidence of arteriosclerosis elsewhere. They suggested a lesion in the brain stem or basal ganglia rather than a localized haemorrhagic or destructive focus affecting the left pyramidal tract in its course between the cortex and mid-brain. Denny-Brown, Adams, and Fitzgerald (1944) support the observation that herpes zoster in the course of generalized invasion may lead to inflammatory thrombosis or haemorrhage.

While the patient remained alive it could be argued that his Parkinson's syndrome was due to arteriosclerosis; this was supported by a psychometric test. The post-mortem examination removed this objection.

In the absence of definite histological findings the evidence presented allows a reasonable assumption that the virus or effects of the virus were responsible: his age; the absence of cerebral arteriosclerosis; the absence of any illness like encephalitis lethargica; and the knowledge that herpes zoster is not necessarily a benign infection, and the relatively high dosage of artane while he was alive.

My thanks are due to Ministry of Pensions Medical Services Division for the results of investigations, and to Dr. R. B. H. Tierney, pathologist.

Reviews

TEXTBOOK OF OBSTETRICS

Textbook of Obstetrics. By John F. Cunningham, M.D., M.A.O., F.R.C.P.I., F.R.C.O.G. (Pp. 499; 297 illustrations. £2.) London: William Heinemann. 1951.

Professor John Cunningham, of University College, Dublin, has written this textbook for students and young graduates. The book is well printed, with many clear headings, and profusely illustrated; yet with its 487 pages of text it is small enough to be easily handled. The writing is clear and to the point, yet gives the reader no impression of being deliberately condensed. A remarkable amount of material is contained in the pages. The author mentions Sheehan's work on anterior pituitary necrosis; Weiner's, Race's, and Fisher's contributions to the subject of erythroblastosis foetalis; the use of penicillin and streptomycin; and much recent work. He finds space for brief historical notes on subjects such as the history of the obstetric forceps, but gives no references to literature.

The illustrations by Dr. T. MacDonald and Dr. O. J. Murphy deserve special mention. Most are crude line drawings, yet they undoubtedly convey the exact impression intended, no more and no less—a merit not always found in more ambitious artistry.

The teaching, although orthodox, is free from the trammels of tradition. In discussing the treatment of eclamptic fits the author states that "chloroform, although much used in the past, is now discarded as too toxic." The puerperal patient is to be "treated as a convalescent from the second day. She may be allowed out of bed to use the commode (placed conveniently to the bed) even when there are many sutures in the perineum." Exercises for the puerperal woman are commended, and "should be done gracefully and gently."

When so wide a field is covered with such commendable brevity criticism is inevitably invited; but in this case criticism can only be benign. More emphasis might be laid on the possibility of rupture of the uterus after classical caesarean section and particularly on the fact that rupture in these cases is often "silent," or nearly so, in its early stages. The advice on the management of breech delivery on p. 321 might be questioned:

"If the breech, whether complete or frank, fails to enter the pelvis, after the second stage of labour has been in progress for a reasonable time with good uterine contractions, disproportion due either to a small pelvis or to a large foetus is the most likely cause . . . If the disproportion is slight or absent, one or more legs should be brought down and labour allowed to proceed."

To the inexperienced practitioner faced with a case in which labour has advanced into the second stage, and in which the breech has still not engaged in the pelvic brim, this counsel might well lead to danger.

The illustrations have already been favourably mentioned. Fig. 150 might usefully be redrawn—or a new figure included—to show the retroverted gravid uterus in the incarcerated state; the existing illustration does nothing to impress on the student the essential features of elevation of the cervix, elongation of the urethra, and distension of the bladder. Figs. 280 and 288 might both be improved; in the first it is doubtful if the "light" grip of the head would enable the operator to rotate the occiput to the front; in the second the positions of the head and of the forceps in relation to the lower-segment caesarean incision are misleadingly oversimplified.

Professor Cunningham has been at pains to present the methods of treatment in obstetrics "in accordance with the Ethical Standards of the Roman Catholic Church." Thus, in discussing the treatment of hydrocephaly, he advises that the head should be tapped with a spinal or long serum needle. "There is no ethical objection," he states, "to employing this treatment as the operation does not kill the infant."

This counsel may not be understood or accepted by all readers, but the ethical considerations will be respected by all. Needless to say, the operation of sterilization receives no mention on any page.

This book is a short and eminently readable exposition of the essentials of the theory and practice of obstetrics. I like it.

J. CHASSAR MOIR.

HOW TO USE THE MICROSCOPE

The Intelligent Use of the Microscope. By C. W. Olliver, A.M.I.E.E., F.R.M.S., M.R.P.S. Second edition. (Pp. 192; 59 figures. 15s.) London: Chapman and Hall. 1951.

This is an excellent introductory handbook for beginners, and the author, with every justification, claims that it combines thoroughness with order and simplicity. He has been at pains to strike the happy mean between "too much theory divorced from its practical implications and the rule-of-thumb type of instruction which remains unexplained." The basic theory underlying magnification, numerical aperture, resolution, and the methods of illumination is discussed at length and in simple terms. There is a valuable chapter on the critical illumination required for photomicrography.

In this edition a special chapter on phase contrast has been included. This method of illumination has entirely done away with some of the most awkward limitations of the microscope because of its capacity clearly to reveal remarkably fine detail in the almost transparent and unstained living cell. The apparatus required for the technique is neither elaborate nor very costly, and the general optical principles underlying this notable advance in microscopical science are clearly explained.

GEOFFREY HADFIELD.

PRAYERS IN HOSPITAL

A Collection of Prayers for Use in Hospitals. (Pp. 218. 4,000 copies free of cost except for postage and packing.*) The General Hospital, Nottingham.

From the General Hospital, Nottingham, comes this book of collected prayers. In addition to the many inspired and varied prayers, this small book sets out, in modified form, suggestions for a set service for each day of the calendar month. Wisely, much has been left to the individual choice of our hospitals. Certain hymns and certain psalms are suggested, certain prayers listed day by day, and the choice is a wide one.

There are prayers for use on special days, there are prayers for cheerfulness, for serenity of mind, prayers too for our hospital staff. Each day has its prayer for thanksgiving, but here let it be noted that, while it is desirable that our patients should give thanks to God, it is asking rather much for the seriously ill patient to give thanks for "health and strength" as worded in the first prayer of the book. Otherwise the prayers are comprehensive, helpful, and imbued with sincere simplicity.

Surely to all our hospitals this book should prove of infinite value. Where daily prayers are customary in the wards, the sister in charge would find this collection of prayers of great help. Alternatively, the service, wherever possible, could be broadcast from a central point in the hospital, reaching every patient at the same time and uniting them in an act of worship.

To many patients may come the wish to study the book at other times, thus drawing to themselves comfort and inspiration during days of enforced inactivity. Indeed, to all patients this book must bring in some degree that spirit of healing which is of such immeasurable importance in helping the work of doctors and nurses.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MARCH 8 1952

CORONARY DISEASE IN DOCTORS

With the present decline in the importance of many of the infectious diseases of childhood—at least as causes of mortality—and with, concurrently, an ageing population, the attention of the epidemiologist is likely to turn increasingly to the ills besetting the middle-aged and old. In the modern sense of the word there is, of course, no difficulty in bringing such diseases into the “epidemiological” net. When taken to comprise always the *group* as opposed to the *individual* aspects of a disease, an epidemiological picture can be drawn of every sickness to which mankind is exposed, just as a clinical picture can be drawn. In diseases of an unknown aetiology such a picture, revealing perhaps an incidence varying in space or in time, in the age of attack or in the occupations of the victims, may well provide a vital clue. The variations, for instance, in the incidence of cancer of certain sites in specific occupations—a group characteristic of the disease—have repeatedly drawn attention to extrinsic factors underlying the production of neoplasms. So far, however, much less has been done to put into an epidemiological setting the other predominant cause of adult mortality to-day—namely, heart disease in its various manifestations. Work in this field will be rewarding, and, to judge by the article in the opening pages of this *Journal*, results may be surprising: the authors have made the startling observation that the incidence of coronary disease in 1947–50 among general practitioners was almost twice as high as the figure for all the rest of the profession—a finding which bears out in a remarkable way the statement in the Spens report about the arduousness of the general practitioner's life.

Dr. J. N. Morris, Mr. J. A. Heady, and Mr. R. G. Barley, the authors of this statistical “thriller,” have taken as their basic data certain records of the Medical Sickness, Annuity and Life Assurance Society, Ltd., a mutual benefit organization which has several thousand doctors on its books. Confining their attention to males of ages 35–64 (since most policies terminate at 60 or 65 and few women belong to the Society), they made it their first task to enumerate

the doctors of different ages exposed to risk in the four years 1947–50, and then to relate to these age groups the number of first attacks of coronary heart disease which were recorded in the same four years. These attacks are shown in the claims to benefit which were presented either for a non-fatal attack which caused an absence from work of at least a week or for a fatal attack irrespective of duration. The incidence rate thus computed reveals its expected steep rise with age from an almost negligible figure under age 40 to one of 12 cases per 1,000 doctors living at ages 55–59 and to almost 17 per 1,000 per annum at ages 60–64—or approximately, in this experience, one first attack a year in each 60 men in this age group.

Turning from attack to death, the authors found that coronary heart disease was in 1947–50 the largest contributor to the mortality amongst this group of men. After 35 years of age about one-third of the total deaths were ascribed to it. The actual death rate rises from approximately one per 1,000 for men in their forties to 7.4 per 1,000 at ages 60–64, figures not very different, it seems, from those that have been published for medical practitioners in the U.S.A. A particularly notable, if not unexpected, feature is the rapidity of death. Of the 48 fatalities here recorded, 29 took place in the first six days of the first attack and another 9 in the ensuing weeks of the first month—in other words nearly 80% of those dying did so in the first month. Therefore, as the authors point out, the greatest need for therapy is in the first few days of the first clinical attack. Such figures also emphasize the great difficulties which must be overcome if an adequate and convincing trial of any such therapy is to be made—for example, of an anticoagulant. The patients reaching hospital are only the fortunate survivors, in whom the prognosis at that stage may not be very unfavourable: it must at the very least differ profoundly from the initial prognosis. A therapeutic trial to be of any real value will call for the collaboration of the general practitioner. It is of no value merely to be “in at the death.”

From these records further light could be thrown upon this question of prognosis by extending the period of observation to cover the decade 1940 to 1950. The history, up to age 65, of all cases occurring in that period of time could be extracted and utilized for this purpose, even though in the earlier years the numbers of doctors at risk was unknown. The authors found 192 such cases—that is, first diagnoses of “coronary thrombosis” in men aged 40–64; and, since division by age suggests no very material changes, it is sufficient to take them as one group. Of these 192 men, 30% died in the first six days and

another 8% in the rest of the first month. Only a further 2% died in the remaining eleven months of the first year. Subsequent fatalities were at the rate of 6% in the second and third years, 3% in the fourth and fifth years, 3% in the sixth and seventh. In short, roughly half the patients had survived three years. Of these survivors of a first attack, about one-third had a second absence from work because of coronary heart disease within the ensuing two years, and about half were attacked again within six years—or, more cheerfully, “about half the men who survived their first illness and returned to work did not have as much as a week’s further sick absence for coronary heart disease in the six years following.”

With angina pectoris, of which there were 42 first attacks, the outlook is very different. Only 11% died within the ensuing five years, and this is the same order of mortality as is shown by those doctors with coronary thrombosis who had had the good fortune to survive the first month.

Other figures of great epidemiological interest can be derived from the basic rates already quoted of incidence and death at different ages. Using life-table methods—in other words, *presuming that the present rates of incidence here revealed will continue unchanged*—Morris and his colleagues estimate that of 1,000 practitioners aged 35 to 45 some 20 to 25 will have a clinical attack of coronary heart disease before age 50, almost another 40 will be attacked between ages 50 and 55, another 60 between ages 55 and 60, and a further 70 between ages 60 and 65. In other words, “medical practitioners under 45 years of age who have not so far been attacked by coronary heart disease have approximately a 20% chance of being attacked before they reach 65.” Similar estimates for the chance of dying give some 70 deaths by age 65 in each thousand doctors setting out from between ages 35 and 45. Though the foundation of these calculations is, admittedly, somewhat slender, it is sufficiently large and sufficiently precise for these figures to give rise to sobering reflection. With events on this scale, “epidemic” certainly does not appear to be a complete misnomer.

How, though, it will be asked, do “doctors” compare with other professional and occupational classes, and how, since their own jobs vary very widely, do they compare with one another? Neither question is fully answered in the present study, but some distinctly intriguing, if interim, figures are presented. It is quite commonly believed that doctors suffer more from coronary heart disease than the rest of the population, but very little convincing evidence has been forthcoming. Impressions based upon the num-

ber of doctors seen by an individual or in a clinic are apt to be inaccurate, and probably, as Morris and his colleagues observe a trifle acidly, “the least reliable impressions are those of distinguished physicians who may have a quite disproportionate number of doctors in their personal practice.” Failing to observe the attractions of their own distinction, they make the wrong generalization. Their deductions may, however, in spite of logical imperfections, yet prove to be right, since the present figures suggest a relatively high incidence in general practitioners though not in the other sections of the medical profession.

In this latter contrast the authors are on definitely safer ground, since all the records come from the one source—the particular assurance society. This comparison, which gives some very unexpected results, was reached by a series of steps, fully described in the report, which were devised with much care and skill to ensure both accuracy and impartiality in the construction of the required rates. Having found, as already remarked, that in 1949–50 the incidence of coronary heart disease upon general practitioners was almost twice as high as the figure for all the rest of the profession and that the other subdivisions within the latter revealed no material contrasts, they sought, critically and with admirable scientific rectitude, for some flaw in their data or in their treatment of it. They failed to detect any red herring. Extension of the figures to cover the years 1947 to 1950, enlargement of the sample of doctors upon whom the occupational distribution was based, an independent check of those occupations—all left the relative incidence rates virtually unchanged. At ages 40–64 the standardized rate per 1,000 was 8.8 cases per annum in general practitioners and 4.4 in other doctors, and this excess was apparent in each age group.

That being so, is this unfavourable position of the general practitioner in 1947–50 a modern or an old-established characteristic of the “herd”? In answering that question the authors were faced with grave difficulties. The age and occupational structure of the population “at risk” in the war years, 1940–6, was not available, and it had to be assumed that it was the same as had been found for 1947–50, but of course in men some years younger. In defence of this assumption they state that the membership of the Society is a very stable one. The statistical calculations based upon it lead to the observation that there was little, if any, excess coronary heart disease among general practitioners during the war years, but that there was an increase of cases among them in 1947–50 which was not paralleled in the experience of other doctors. This increase does not appear to be due

merely to improving diagnosis in the one group compared with the other, since fatal and non-fatal attacks have equally increased. Beyond those tentatively drawn conclusions the authors cannot, and wisely do not, attempt to go. They emphasize instead the importance of further work, and its extension, beyond the records of the particular assurance society to which their study was confined, to the whole medical profession. It should be profitable, they suggest, not only to explore the antecedents of coronary heart disease among doctors and to expand the clinical picture of it, but also, through the field survey approach, to investigate the possible associations and relationships of the disease. For "Physician, heal thyself" we must perhaps substitute to-day the less euphonious "Physicians, epidemiologically survey yourselves." Dr. Morris and his colleagues have made a good start, and it is to be hoped that with the co-operation of the profession the Medical Research Council's Social Medicine Research Unit will be able to expand its work and carry out systematic studies on a large scale, with the aim of preventing a disease which numbers so many doctors among its victims.

SUPERINFECTIONS DURING ANTIBIOTIC TREATMENT

The term "superinfection" has come into use to describe fresh complicating infections arising during antibiotic therapy. An initial response to treatment marks the overcoming of the original infection, to be succeeded by a worsening of the patient's condition, accompanied by the appearance of bacteria resistant to the drug which were not found before. These bacteria may be presumed to have been present in small numbers before treatment began and to have found an opportunity to multiply in the circumstances so produced. The obvious circumstance resulting from antibiotic treatment, apart from action on any specific pathogen, is the suppression of the general flora of certain areas of the body: Penicillin exerts this suppressive action mainly in the mouth, owing to its excretion in the saliva, and it is well recognized that in patients receiving heavy doses of this drug streptococci and other bacteria in the mouth are largely replaced by coliform bacilli. Superinfections during penicillin treatment are for the same reason chiefly liable to involve the air passages. The newer anti-

biotics affect in this way not merely the mouth but the entire alimentary tract, since they are not only administered by this route but also incompletely absorbed. From studies such as those of Bierman and Jawetz¹ it is known that in a patient taking "aureomycin" (chloramphenicol has a less pronounced effect) most of the normal intestinal flora are suppressed for as long as treatment continues, but to some extent replaced by *Pseudomonas*, yeasts, and staphylococci resistant to the drug.

In view of this much more widespread interference with the normal bacterial population of the body it is not surprising that superinfections occurring during the course of or after treatment with these newer drugs have excited much more attention. They are in fact quite common during prolonged treatment, taking the form of a glossitis or an affection of the anal region caused by *Candida (Monilia) albicans*. This yeast-like fungus is highly resistant to all known chemotherapeutic agents. It was because such infections may take a more serious form, spreading from the mouth to the bronchi and lungs, that the Council on Pharmacy and Chemistry of the American Medical Association decided last year that a warning statement must be printed on the packages of these drugs in the U.S.A., a somewhat startling procedure to which reference was made at the time in these columns.² Our comparative inexperience of such conditions in this country is due simply to the scarcity here of some of the drugs causing them, although minor manifestations such as glossitis have become familiar. What may be an example, and an unusual one, of such a superinfection is reported by Drs. J. D. Abbott, H. V. J. Fernáudo, K. Gurling, and B. W. Meade on page 523. A patient with post-influenzal bronchopneumonia was found to have *Bact. coli* and *Candida albicans* in her sputum: it is not stated that she had had treatment with penicillin during the preceding three weeks of the illness, although such a finding would lead one to suppose it. Despite treatment with penicillin, streptomycin, and chloramphenicol she died, and was found at necropsy to have cavitating pulmonary aspergillosis, although the presence also of *C. albicans* in the lung cavities was confirmed. It is of course possible that the *Aspergillus* infection existed before antibiotics were given and would in any case have been fatal, but when such a condition makes its appearance during the administration of drugs to which the causative organism is wholly insensitive the suspicion that the treatment was doing positive harm cannot be put aside.

More information is needed about the mechanism whereby resistant bacteria and fungi are enabled to

proliferate and cause lesions during antibiotic therapy. It may be that the suppression of the other flora of the area either upsets a balance normally holding them in check or simply provides them with more pabulum. On the other hand, there is more than a suspicion of positive stimulation to active growth by the antibiotic itself. There is much evidence, recently reviewed by Garrod³ in this *Journal*, that sublethal concentrations of antibiotics as well as other noxious agents accelerate the growth of bacteria, particularly of resistant species. Directly bearing on the present problem are the findings of Foley and Winter,⁴ who showed that treatment with penicillin increased the mortality from *C. albicans* infection in the chick embryo. Pappenfort and Schnall,⁵ who reported *C. albicans* infection in 16 patients treated with aureomycin, also found that this drug stimulates the growth of the organism *in vitro*. On the other hand, its growth was also stimulated by solutions in which aureomycin had been destroyed by heat or alkali, and it was unaffected by a pure preparation intended for parenteral injection. They therefore concluded that an impurity was responsible for this effect. Evidently the full truth of this matter is not yet known. Meanwhile we shall be well advised to remember that, although the products of some species of fungi have revolutionized therapeutics, there are other species causing infections which are among the very few still quite unaffected by any form of chemotherapy.

PSEUDOCYESIS

The woman who firmly but falsely believes herself pregnant and in whom develop many of the symptoms and some of the signs of pregnancy was known to Hippocrates, while the clinical picture drawn by Sir James Simpson in 1860¹ has never been bettered. The reported cases of this medical curiosity total fewer than 500, but, as Simpson wrote, it is "of far more frequent occurrence than the comparative silence of our textbooks on this malady would lead you to infer." This is because most of the cases without very remarkable features are not reported, the patient being merely informed sooner or later that she is not pregnant without any deeper search into the origin of her disorder. After being thus dismissed she may go on to trouble another doctor. Fried and his colleagues² have recently reported a series of 27 cases of pseudocyesis in which the women, all but one of whom were childless, were examined for endocrinological and psychiatric as well as gynaecological defects. Spurious pregnancy is generally considered commoner in women near the meno-

pause, but Simpson often found it in younger women; and the majority of Fried's patients were in the middle twenties. These patients possess most of the usual symptoms of pregnancy, but hypomenorrhoea is more common than amenorrhoea. One of the most notable features is the appearance of characteristic signs of breast activity, including secretion, even in nulligravidae, but in none of Fried's cases were the uterine or cervical changes typical of true pregnancy. Yet women with pseudocyesis pass superficial examination for pregnancy with ease, chiefly because the possibility of the condition being spurious is not considered, and once the diagnosis of pregnancy has been made the symptoms flourish. In fact such women have been operated on for supposed ectopic pregnancy and even for placenta praevia.³ Moreover, the symptoms may continue for years rather than months. Simpson relates that Dupuytren, when asked by a lady who insisted she had been pregnant for 14 years, what course she should follow, answered that as the boy must be tolerably well grown by that time the best thing the lady could do was to swallow a tutor, that his education be not neglected.

Fried regards pseudocyesis as a form of conversion hysteria and remarks on the frequency with which the syndrome follows an emotional strain which the patient believes can best be relieved by a pregnancy. A picture of pseudo-pregnancy can sometimes be induced by the administration of gonadotrophins, alone⁴ or in conjunction with oestrogen and progesterone⁵; but this differs from pseudocyesis in that if the psychic factor and predisposition are not present the signs do not become progressive, and there are no complaints of morning sickness, enlargement of the abdomen, and "foetal movements." Fried and his colleagues concluded that the amenorrhoea in pseudocyesis is hyperhormonal, whereas most forms of psychogenic amenorrhoea are hypohormonal. In particular, evidence of progesterone activity in most of the women seemed to point to persistent corpus luteum function. This is not a new idea, for Simpson wrote 90 years earlier, "Perhaps we would find the corpora lutea tending to simulate in their development and growth the corpora lutea of pregnancy." But Fried goes further and propounds a hypothesis that the basic mental conflict which appears best solved by pregnancy affects the pituitary by way of the hypothalamus. The reaction in the anterior pituitary, he conjectures, leads to secretion of the luteotrophic hormone at the expense of follicle-stimulating hormone, and the result is persistent luteinic function in the ovary, which could account for most of the clinical features. Whether this hypothesis is correct or not, it remains a fact that, except in minor degrees of the syndrome, merely telling the patient she is not pregnant is insufficient treatment, for either the woman is unconvinced or, after an interval, further symptoms of pseudocyesis bring her again to the doctor. Fried therefore recommends psychotherapy, in order that the patient may obtain an insight into her condition. The best evidence of cure is the return of normal menstruation, the absence of recurrence, and, best of all, a true pregnancy.

LONDON'S WATER SUPPLY IN WARTIME

A report¹ recently published by the Metropolitan Water Board describes the steps taken to maintain an adequate and wholesome supply of water during the war years. The author is Lieutenant-Colonel E. F. W. Mackenzie, the Board's director of water examination. Two schools of thought existed when defence plans were being prepared before war broke out: one considered that it was unnecessary to take precautions against disasters which might not occur; the other maintained that every practicable precaution should be taken to provide against any contingency. Fortunately for the people of London the second view prevailed, and how amply it was justified is set out clearly in the pages of the report. The emergency plans of the Board were concerned first with the repair of mains damaged or broken by bombing (it took some time to discover that concussion from bombs exploding some distance away could fracture water mains without affecting the ground above them); secondly, with ensuring that laboratory tests could quickly be carried out in order to estimate the purity or otherwise of the supply after damaged mains had been repaired; and, thirdly, with the purification by the quickest possible method of repaired water channels after they had been contaminated by sewage. The value of prechlorination—chlorination before filtration—in such times of emergency was proved beyond any doubt, as will be appreciated by all who read the report. So successful was this procedure that in some places the old river intakes (for instance, at Hampton) were opened, and unstored river water was led to the filters. Steps were taken to protect wells also, though fortunately none of the Board's wells was very seriously affected by bomb damage.

The policy of the Board was that no repaired main should be brought back into service without prior disinfection. The methods of disinfection were remarkably successful. Samples were examined from 807 of the 875 large mains which were fractured by bombs, and of these 801 (99.3%) were negative to *Bact. coli*. Of the six which fell below this standard, five contained fewer than 10 *Bact. coli* in 100 ml. The Board's work in fact was so efficient that even in official quarters some credence was given to a dangerous fallacy—that the non-appearance of epidemics meant that the dangers to the population from polluted water had been exaggerated. The report also describes the measures taken to guard against the contamination of water stored in reservoirs by the dropping of bombs charged with such materials as poisonous gases. Daily testing of the water was continued as a routine throughout the war, and on no occasion was there any evidence that poisonous matter had gained access to it. Apart from its technical interest the report is a tribute to the loyal devotion of the members of the team who performed a vital task under very difficult circumstances during six years of war.

VITAMIN-A POISONING

When some writers are warning us of the calamitous results of over-population in a world short of food, and when vast numbers of people are unable to obtain even the minimum of food necessary for survival, it is slightly ironical to read of syndromes caused by over-dosage with vitamins in children. The increased knowledge of nutrition and the special stresses of war have led to the publication of innumerable books and papers on nutrition, both scientific and popular. Some parents, impressed by doubtful evidence of subclinical deficiencies or perhaps even more by skilful advertising, have apparently been concerned to see that their children, at least, shall be free from these preventable illnesses and have given them large and sometimes enormous doses of vitamin preparations.

Reports¹ of vitamin-A poisoning in animals appeared as early as 1933, but the first observation² of harmful effects in a child was not reported until 1944. A recent article³ lists 17 recorded cases, and it is probable that many others have occurred without being diagnosed or reported. Most of the children received about 250,000 U.S.P. units of vitamin A daily for many months, and one had twice this daily dose for 16 months. All the children were more than 1 year old, perhaps because vitamin-A preparations are not very well absorbed in young infants⁴ or because of the relative tolerance to large doses. The symptoms are fairly constant and include irritability, anorexia, loss of hair, pruritus, and painful extremities with tender swellings. Radiographs of the long bones show cortical thickening, especially of the ulnae. Biochemical examination of the blood is generally negative, although in some cases the alkaline phosphatase has been high. The amount of vitamin A in the plasma has been high enough for the condition to be diagnosed in all cases. The symptoms disappear within a very few days after administration of the vitamin is stopped.

The differential diagnosis is difficult, largely because of the rarity of the condition. Leukaemia, scurvy, and congenital syphilis present pictures similar in some ways, but fairly easily distinguished, and vitamin-D poisoning is also similar and may indeed coexist to some extent, since the source of the vitamin intake usually contains large amounts of vitamin D as well as vitamin A. Caffey's syndrome⁵ bears most resemblance clinically, but there is no history of excessive dosage with vitamin A and the amount of the vitamin in the plasma is normal. There is usually some degree of fever, and the mandible is always involved in the periostitis. Unfortunately the published case records do not discuss the reasons which prompted the parents of these children to give such enormous doses of the vitamin; these might have thrown some light on the effect and effectiveness of methods of education of the public in medical matters.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

CLINICAL ASSESSMENT OF BACKACHE

BY

J. G. BONNIN, M.B., F.R.C.S.

Orthopaedic Surgeon, Central Middlesex Hospital

An ordered approach to the subject of backache is difficult to achieve. In spite of the discovery about 16 years ago of the prolapsed disk syndrome we are still left with many cases in which speculation replaces certainty, and in which there is no agreement on pathology, diagnosis, or treatment. No matter how one approaches the

imposed on a structural deformity of the spine, and the first point in the clinical examination is an attempt to separate defective posture due to spasm from that due to a fixed bony deformity. This can usually be done by careful inspection of the spine while the patient is bending forward, or by noting the obliteration of the deformity when he is lying on the face completely relaxed (Fig. 1).

Fig. 1.—Muscle spasm but no obvious skeletal defect.—(a) A typical sciatic scoliosis showing a lumbar deviation to the left. (b) On bending forward the scoliosis usually increases and the patient tends to flex the affected knee. In this case, which is unusual, the scoliosis has altered to the opposite side: this is a recognized occasional variant. (c) This shows almost complete obliteration of the scoliosis on lying down, indicating that the primary cause is muscle spasm.

possible causes of backache, there remains an indefinite fringe of cases in which no certain diagnosis is possible. This group is characterized by either an absence of clinical findings or a clinical finding of painful muscular spasm for which there are alternative explanations.

Wherever the seat of the primary disorder may be, it manifests itself to the consciousness in three ways: (1) well-localized pain accompanied by areas of tenderness to pressure—for example, over the spinous processes or a muscular attachment; (2) pain due to pressure on nerve trunks which is felt at a distance over the dermatome supplied by the nerve; and (3) referred pain due to a "spread-over" at higher levels in the nervous system from sources of pain which have no cortical representation—for example, interspinous ligaments, intervertebral disks. A precise anatomical diagnosis can usually be made in the first two groups. In the third group, in which the pain is referred, difficulty arises, and often there is accompanying muscle spasm.

Muscle Spasm or Structural Deformity?

Muscle spasm usually produces a constant pattern of deformity—a flattening of the lumbar spine on standing, increased tone in one or both erector spinae with limited lumbar flexion, and a scoliosis of the spine increased by flexion. We often find that the patient with muscle spasm is reluctant to bend with both knees straight, but is able to bend with one knee flexed, and that he has a slight reduction in extensibility of the spine. This pattern is most marked in acute protrusion of an intervertebral disk with root pressure. Muscle spasm may or may not be super-

Fixation of the spine in a normal anatomical position, such as may occur in the early stage of spondylitis ankylopoietica, is easily overlooked. Likewise, muscle spasm alone may so fix the spine that there appears to be a structural rigidity. Here it is important to note a few further characteristics of the deformity produced by muscle spasm alone. The spasm is usually unequal, so that forward flexion is disproportionately limited to lateral flexion of the spine and to rotation. When the patient is placed on a couch the spine relaxes and the normal lordosis of the spine reappears or the scoliosis straightens. Such observations exclude the presence of a fixed structural deformity. Unfortunately they do not exclude the presence of spinal abnormality, and in the last resort this can be excluded only by radiography. While this is often necessary, especially in cases with significant clinical features such as recent trauma or a history of pulmonary tuberculosis, wasteful radiography can be avoided only if those cases in which an x-ray picture is unlikely to be helpful are excluded.

Clinical Classification

On the basis of whether muscle spasm and structural deformity are present all cases of backache can be grouped as follows: (1) Obvious skeletal defects and no muscle spasm (Fig. 2)—for example, spondylitis ankylopoietica, healed tuberculosis, and postural deformities. (2) Obvious

Fig. 2.—Obvious skeletal defect but no muscle spasm. (a) A marked thoracic kyphosis and lumbar lordosis in an elderly patient unaware of a long-standing spondylitis ankylopoietica. (b) On forward bending the curves of the spine remain unchanged. There was an associated gross limitation of lateral flexion and rotation of the spine.

FIG. 3.—Muscle spasm masking a definite skeletal defect. (a) Flattening of the lumbar spine due to erector spinae spasm without scoliosis. (b) Limitation of flexion and persistence of spasm on forward bending. (c) Relaxation of the spasm on recumbency, with the appearance of small kyphosis at the lumbo-dorsal junction which was confirmed radiologically to be due to early tuberculosis of the spine with destruction of a single intervertebral disk.

skeletal defects with muscle spasm (Fig. 3)—for example, active tuberculosis, and aggravated osteoarthritis. In this group the deformity is primarily bony and not caused by the spasm. The spasm may serve to show the degree of activity of the underlying disease. (3) No obvious skeletal defect and no muscle spasm—for example, referred pain from visceral causes, poliomyelitis, and hysterical spine. (4) No obvious skeletal defect and muscle spasm (Fig. 1)—for example, lumbago, and prolapsed intervertebral disk. The largest proportion of cases fall into group 4, and to begin with can be safely treated at home, where observation of their reactions to rest in bed will prove a useful guide to the necessity for further investigation.

Cases with Negative Clinical Findings

The most difficult cases to diagnose may belong to group 3, with negative clinical findings. As clinical examination is so inaccurate in the spine, supplementary radiography is needed. This may result in cases falling into group 1, although the changes in the spine are minimal and only recognizable by radiography. Spondylolisthesis and other developmental abnormalities around the lumbo-sacral junction, early tuberculosis, and localized osteoarthritic changes around a single intervertebral disk are examples of conditions which may be brought to light only by radiography.

Where no assistance is given by radiography the problem may be insoluble, or the answer may be provided only by watching the progress of the disease. It is in this type of case that the history is of primary importance to exclude the visceral causes—for example, renal, gastric, and pelvic disease; to assess the patient's personality in cases following injury in which there may be malingering or hysteria; and to elicit the relationship to pregnancy and the puerperium in the post-natal backache of young women.

Cases with Muscle Spasm Only ("Lumbago")

The cases in group 4, with muscle spasm but no deformity, are usually classed together as "lumbago." From this group must first be separated those cases due to prolapsed intervertebral disks. This can usually be done by noting the characteristic type of pain: severe aching pain, radiating over a recognized dermatome, often with sciatic pain as well as backache; aggravation of the sciatic pain on coughing, sneezing, or postural changes; complaints of numbness and tingling; and periods of sudden relief, or aggravation.

Examination may show: altered sensation—hyperaesthesia or impaired sensation over a dermatome; absence or diminution of a knee-jerk or ankle-jerk; wasting and loss of tone in the glutei, hamstring, or calf muscles; loss of

muscular power in the calf, extensors of the toes, tibialis anterior, and peronei; areas of deep tenderness in the buttock and calf on the affected side; and increased pain on stretching the sciatic nerve (Lasègue's sign and its variations).

Radiological confirmation of changes in the disk space are comforting to the diagnostician, but the essential basis of diagnosis of a prolapsed intervertebral disk remains neurological. Two groups can be recognized: those with objective neurological signs, and the less satisfactory but equally common group with subjective signs only. Where these are characteristic and supported by skeletal signs the diagnosis is definite, but there may be an indeterminate group in which the distinction between acute "lumbago" and prolapsed intervertebral disk remains impossible until the case has been observed for some time, when positive neurological or radiological findings may appear.

After thus excluding prolapsed intervertebral disk as completely as possible there then remains the analysis of the other causes of muscle spasm in the back. These cases form a rather unsatisfactory group. They may be divided up into myofascial strain, paroxysmal "lumbago," and fibrositis or myofibrositis.

Myofascial Strain.—The alternative diagnosis to this is a minor disk injury, and this cannot be disproved. Myofascial strain is characterized by a history of strain either by lifting a heavy weight or by lifting in a bent position; a feeling of something snapping in the spine; localized pain on pressure to the side of the spinous processes; recurrence of pain on attempting to straighten from the flexed position; a vague radiation of pain, often bilateral, which never goes below the knee; and recovery with rest and physiotherapy in seven days or less. The diagnosis is seldom confirmed by observation of a haematoma, though there may be an occasional palpable thickening in a muscle. The tenderness is well localized, and complete temporary relief can usually be achieved by procaine infiltration.

Paroxysmal "Lumbago."—This may be related to overwork or unusual work. There is seldom any definite injury, and the condition may be recurrent in certain individuals. Repeated examinations often show osteoarthritic changes in the spine in later years of life which are disproportionate to the age of the patient and these may be the basic cause of the attacks. It is characterized by an onset when the patient is flexed and an inability to straighten up; a pain worse on attempting to straighten the back, but the patient can overcome his fears enough to bend forward; a severe pain that has some of the features of cramp, although the individual is not frightened by it and often feels he would like to laugh at himself; an immediate alteration in the quality of the pain after deep massage, with restoration of full or almost full extension; and complete recovery within a week or less.

Fibrositis or Myofibrositis.—The onset of the pain in these cases is usually more gradual. The patient may have had similar attacks elsewhere—for example, recurrent stiff neck or fibrositis of the trapezi. It is characterized by slow development sometimes associated with a cold or mild influenzal attack; a tendency for signs to be bilateral—for example, the spasm may involve both erector spinae without flattening of the lumbar spine; areas of tenderness in the muscles that may change from day to day; localized areas of thickening or tenderness over certain recognized areas, notably the twelfth ribs, the lumbo-dorsal fascia, and the iliac crests. Similar tender areas may be found in other muscles at a distance—for example, the trapezi. The recovery is slow, possibly taking two to three weeks, but is complete.

Complete recovery is characteristic of these three groups. A course of rest in bed, local heat, hot baths, and analgesics is therefore not only good treatment but a useful step in confirming the diagnosis. If recovery does not occur within a week a course of more active physiotherapy is helpful. Radiant heat followed by deep massage and extension exercises of the spine will clear up the residual pain in all but a small group of cases.

Severe Pain

Severe pain in the back may be alarming to the patient and may result in behaviour which causes a suspicion of hysteria. Assessment of the patient's personality is therefore important, remembering that, in general, severe back pain is not a common presenting symptom of hysteria. The following conditions may have to be excluded: acute disk prolapse with severe sciatica; acute prolapse of a disk into the vertebral body without nerve-root pressure; early tuberculous disease, in which the pain is sometimes nocturnal, occurring when the patient relaxes in bed; and collapse of a vertebral body due to any destructive lesion such as a secondary malignant deposit or myeloma. Severe pain unrelieved by rest demands early radiological examination, though rapid recovery with rest is the general rule.

Conclusion

While it is true that the diagnosis of many cases of backache demands radiography, this examination will be negative in almost half of the cases submitted to it. The simple lines of assessment indicated here will enable a satisfactory clinical diagnosis to be made in the first instance, and this can be modified by observing the patient's reaction to rest in bed and simple comforting domestic measures. It is better to diagnose a case as "lumbago" and treat it as such than to alarm the patient with the current bogey of disk prolapse and to send him to hospital for investigation. In most cases the first line of investigation in hospital will take the form of observing the patient's reaction to rest in bed.

Next Refresher Course Article.—"Food-poisoning," by Dr. Joan Taylor.

The Department of Health for Scotland recently issued a circular to local authorities containing suggestions for improving the welfare arrangements for old people. Many of the points made may seem rather obvious, but they have not hitherto been summarized in this way. Helpful suggestions are included on how to meet the needs of old people living at home. Briefly, the circular deals with three main problems: old people suffering from neglect in their own homes, the provision of meals for such people, and the use of hospital and residential accommodation for them. One way of meeting the first problem would be the publication locally of the name of the official to whom such cases should be reported, and those local authorities who have not already done so are advised to keep a list of old people, needing attention, who live at home in the area. Health visitors should be used as part of every welfare scheme for the old. A separate memorandum enclosed with the circular discusses the organization of meals services; these should be provided by voluntary effort supported by local authorities. No good reason is seen for charging less than 9d. for a normal meal, as the National Assistance Board can help anyone receiving meals because of special needs. The memorandum emphasizes that the aim of a meals service is not in any way to discourage relatives living within reasonable distance from fulfilling their normal family duties. Finally, the present statutory position is that responsibility for deciding the admission of an old person to hospital or local authority accommodation rests with the hospital or the local authority. Failing the one, the other must be responsible.

THE BRAIN AS A MACHINE

SIR HENRY COHEN'S ROYAL INSTITUTION DISCOURSE

The Friday evening discourse at the Royal Institution on February 29 was given before a distinguished company by Sir HENRY COHEN, who addressed himself to the theme, "The Brain as a Machine."

The history of this problem, he said, dated back to Descartes and his period, the first half of the seventeenth century, when the mechanical laws of the "physical" world were being elucidated. Descartes postulated reflex action as explaining movements in which brain and nerves played an essential part, but he realized that man was more than such an automaton, and he regarded phenomena such as memory, judgment, and decision as properties, not of the brain, but of the "spirit" or psyche. Cartesian dualism conceived the human being as body and mind; the body, which was material, could be known perceptively and obeyed the laws of physics and chemistry, while in contrast the mind was not subject to mechanical laws and was only to be known introspectively by its possessor, or, if known to others, only by behaviour, the inferences from which might be misleading. The brain was regarded as the control exchange through which the mind influenced any part of the body.

The physician, said Sir Henry Cohen, was at the outset prejudiced against this conception. He saw a patient whose memory for recent events was clouded, who was indecisive, slovenly, nervous, depressed, but whose behaviour, after a brain tumour had been removed, returned to normal. He saw a child victim of lethargic encephalitis, who before the illness was well behaved, but afterwards lost moral control and developed aberrations. These disturbances were the result of organic disease of the brain and disappeared when the structural damage was made good.

The Biological Approach

In the seventeenth century physiological phenomena were explained in terms of levers, pulleys, pumps, and the like, but, although these might be accepted as representing muscular movements and movements involved in circulation, not very much of what the brain did could be explained in that manner. The experimental biologist applied the techniques of physics and chemistry to the living organism. This approach was exemplified by Loeb's tropisms, Pavlov's conditioned reflexes, Watson's behaviourism, and Lashley's work on the localization of the "engram." But the story was far from complete, and the approach by analogy was not without its dangers.

Another approach was to see what machines could accomplish. During the last 10 or 20 years electronic computing machines had been developed and these appeared to possess many supposedly rational properties of mind. Sir Henry gave an astonishing list of what such machines could do. They could learn what they were told, apply instructions when needed, read and remember numbers, add, subtract, multiply, and divide, carry out a long chain of operations one after the other, write out the answers, and—an attribute not entirely human in these days—work unattended. They stored in some form the results of preliminary calculations, a process analogous to memory, and made use of the results at the right time. These machines might be only in their infancy. One saw them handling the routing of telephone calls, translating from one language to another, even making strategic decisions in simplified military operations. The answers they gave were not simply "yes" and "no," but more flexible.

A Clue to Brain Mechanism

The question was how far these automata afforded a clue to the mechanism of the brain. Were the structure and function of the nervous system, so far as known, consistent with the action of an electronic machine? Recent electro-

The effects can be lessened

When the storm clouds gather in the mind of the woman at the menopause, much can be done to alleviate her apprehension and to ensure that she sails through the difficult years on an "even keel."

Euvalerol M, the ideal sedative in menopausal conditions, alleviates nervous phenomena and vasomotor disturbances and helps the woman at the menopause to weather the storms of emotional imbalance.

Composition : Euvalerol M contains a preparation obtained from valerian root from which the unpleasant odour characteristic of valerian is eliminated. To each fluid drachm (4 c.c.) of this odourless preparation of valerian are added $\frac{1}{2}$ grain (16 mg.) of phenobarbitone and 0.1 mg. of stilboestrol.

Presentation : Euvalerol M is supplied in bottles containing 4 oz. and 8 oz. It is also available in bottles of 20 oz. and 80 oz. for dispensing purposes.

EUVALEROL M

Literature on application.

Aqueous Suspensions of B.D.H. Sex Hormones FOR QUICKER ACTION AND PROLONGED EFFECT

These new B.D.H. Products consist of suspensions of oestradiol monobenzoate, progesterone and testosterone propionate respectively in saturated aqueous solutions of the hormone. Aqueous suspensions have the following advantages:

1. Prompter action than that obtained with oily solutions.
2. Duration of effect is somewhat longer than with comparable doses of oily solutions.
3. Finer needle can be used.
4. Injection is painless.
5. Syringe need not be thoroughly dried before use.
6. Absence of oil makes syringe easy to clean.
7. Dosage is the same as for oily solutions.

'OESTROFORM' AQUEOUS Oestradiol Monobenzoate B.P. in aqueous suspension (Ampoules containing 1, 2 and 5 mg. in boxes of 6 ampoules)

'LUTOFORM' Progesterone B.P. in aqueous suspension (Ampoules containing 5, 10 and 25 mg. in boxes of 6 ampoules)

'TESTAFORM' Testosterone Propionate B.P. in aqueous suspension (Ampoules containing 5, 10 and 25 mg. in boxes of 6 ampoules, and 50 mg. in boxes of 3 ampoules)

"C.P.L." ANTIPRURITICS BREAK THE "VICIOUS CIRCLE" OF PRURITUS

polycrest antipruritic cream

Phenylmercuric nitrate 0.25%
Amethocaine 0.50%
Benzocaine 5.00%

action: bacteriostatic and fungicidal combined with prompt and sustained surface anaesthesia.

indications: pruritus ani and vulvæ, tinea and pruritic conditions of diverse origins in both sexes.

menopax antipruritic cream

Stilboestrol 0.10%
Amethocaine 0.50%
Benzocaine 5.00%

action: local oestrogen therapy combined with prompt and sustained surface anaesthesia.

indications: menopausal pruritus vulvæ, senile vaginitis, pruritus vulvæ during pregnancy, etc.

C.P.L. preparations have no B.P., B.P.C., or N.F. equivalents and may be freely prescribed as they comply with the relevant recommendations of the Cohen Report.

Supplies: 20 grams, 4 oz. and 8 oz.

Professional samples and literature on request

physiology had revealed that the brain showed significant electrical changes during its activity. They had only to recall the work of Adrian to realize how beautifully these had been discovered. Electrical changes did take place in the brain, but were, of course, extremely difficult to analyse. The interconnexions of the nerve cells were of almost unimaginable complexity.

It was only right to say that as yet there was very little evidence that the central cortical mechanisms were those of an electronic machine. The evidence was incomplete, and in some respects quite easily controvertible, especially some evidence put forward by enthusiasts; nevertheless, the structure of the cortex was not inconsistent with such a supposition, and indeed by hypothesis a number of mental phenomena—memory and so forth—could be explained in that way. But, assuming that the brain did act like an artifact (in the sense of an artificial construct), what was the relationship of the brain machine to the “mind,” the “thinking component” of Descartes? If it were accepted that the brain might act like an artifact, then many characteristics which had been accepted as those of abstract mind must be considered as belonging to the brain—for example, memory, recollection, purposive action, communication, prejudice, preference, the weighing of evidence, the formulation of hypotheses and universals. There were many who were prepared to believe that an artifact could do all the things claimed for it so far as mental processes decided by mathematical symbols were concerned, but that a machine could never be made which would fall in love, or enjoy a wine, or write a sonnet, or cast a vote, with all the irrational conduct that implied. But as more was learned of brain physiology more attributes formerly assigned to mind might be transferred to mechanistic abstractions. Lord Samuel had pictured a chess player cogitating whether to sacrifice a queen, and stretching out his hand to make the move, and said that the physiologist could describe the mechanistic movement but not the process which decided the choice. Yet even while that was spoken a chess machine which would play a human opponent was being completed.

In conclusion Sir Henry Cohen said that he could not hope to present such a thesis without obscurity or dogmatism; this was imposed by limitations of time. But it must be understood that there was still a long way to go in attempting to explain functions regarded as “mental” in terms of “brain” regarded as a machine. It was probable that our abstractions of brain and mind were not appropriate to solve in its modern setting this problem which had for so long been posed. Quite different abstractions were required to resolve the difficulty. Despite recent papers, he doubted whether semantic studies alone would suffice to give the clue. What were needed were not only new words but new ideas—a new “thinking cap”—if a satisfactory answer was to be found to the question: “Is the brain a machine?”

Reports of Societies

INSECTICIDES TO-DAY

A symposium on insecticides was held by the Royal Society of Tropical Medicine and Hygiene on February 21 at Manson House, W.I. The President, Sir Neil Hamilton Fairley, was in the chair. Six papers, which were not read at the meeting but had been available to persons interested, formed the basis of the discussion.

Factors Affecting Success

In the first paper Professor G. MACDONALD described the objectives of residual insecticide campaigns. In the prevention of malaria the degree of insect mortality which

must be attained for success varied with the number of mosquitoes, the frequency with which the species concerned bite man, and the duration of the extrinsic cycle. Differences in these factors, and particularly in the man-biting frequency, greatly affected the degree of mortality necessary to secure control of the disease. His paper was illustrated by a nomogram which showed the interaction of the variables discussed. He also discussed briefly the factors involved in the eradication of mosquito species as distinct from eradication of malaria. Finally Professor Macdonald mentioned a few subjects in this field on which further research would be profitable.

Dr. A. B. HADAWAY and Mr. F. BARLOW described some of the physical factors affecting the efficiency of insecticides. To destroy insects protected by forest canopy aerosol particles larger than $100\ \mu$ were useless, as they did not pass the first barrier of leaves. Particles measuring $10\text{--}40\ \mu$ were more efficient. If oil solutions were applied to absorbent materials, such as the walls of the mud dwellings so often found in the Tropics, insecticide was lost by penetration. There was also a loss of insecticide when mud was sprayed with aqueous suspensions of wettable powders, though the duration of effectiveness on different muds might vary.

The resting habits of insects had to be considered when preparing insecticidal schemes. Contact with D.D.T. (dichlor-diphenyl-trichlorethane), for example, might repel a mosquito before it had acquired a toxic dose. Though mosquitoes might similarly be stimulated to flight by contact with “gammexane” (gamma isomer of benzene hexachloride), the toxicity of that substance was such that they usually acquired a lethal dose from treated surfaces.

The Newer Insecticides

Dr. J. R. BUSVINE described the newer insecticides. Of these he stated that D.D.T. analogues and “toxaphene” were unlikely to replace D.D.T., except in special circumstances where the very low toxicity of certain of the D.D.T. analogues was an important consideration. As a residual-film insecticide, “dieldrin” should be excellent, as it combined the persistence of D.D.T. with the high insecticidal power of gammexane. Though these insecticides differed in structure they could be grouped together as chlorinated hydrocarbons, and houseflies which developed resistance to one of them might be found to have also become resistant to others in the group. Among non-chlorinated hydrocarbons, “parathion” (diethyl-*para*-nitrophenyl-thiophosphate), an organic phosphorus compound, was the most promising insecticide, though it was more toxic to man than D.D.T. and less effective against bed bugs. In general, compounds of this type were highly toxic to arthropods and to vertebrates, but not very stable or persistent. They might be useful for some agricultural purposes. “Allethrin,” a synthetic compound allied to pyrethrins, could be used in the same way as the natural products; it had a better residual action and was free from resinous impurities.

Resistance

Dr. C. M. HARRISON, in describing the resistance of insects to insecticides, said that within the last four years D.D.T.-resistant fly populations had developed in many parts of Europe, the Middle East, and America. Such flies might also be resistant to other insecticides of the chlorinated hydrocarbon type. Though morphological differences between D.D.T.-resistant and susceptible flies had been reported, agreement about that was lacking. Physiological differences were, however, more likely; thus resistant flies metabolized D.D.T. into the non-toxic substance D.D.E. (an ethylene derivative), whereas susceptible flies did not. This process would not, however, fully explain resistance, as living resistant flies after exposure to D.D.T. might contain enough D.D.T. to kill normal flies. Resistance was clearly inherited, since D.D.T.-resistant flies gave rise to resistant progeny in the absence of the insecticide; the

mechanism of inheritance of this character, however, was complex. There was no good evidence of resistance having yet developed in anopheline mosquitoes.

For the control of resistant species the prevention of breeding by hygienic measures was recommended rather than the use of many insecticides.

Toxicity to Man

Dr. J. M. BARNES described the action of some synthetic insecticides on man. A few cases of serious poisoning had resulted from the accidental contamination of food with D.D.T. The symptoms included headache and dizziness. In animals poisoned with D.D.T. or gammexane no histological changes had been detected in the nervous system despite the obvious evidence of severe derangement of function. Necrosis and fatty changes might develop in the liver. "Chlordane," "aldrin," and dieldrin in toxic doses acted as convulsants and also produced liver changes. Phenobarbitone might prevent the convulsions, but it did not detoxicate the insecticides. Aldrin had recently been widely used against locusts in Persia, and despite repeated exposure to oily solutions there had been no human casualties.

Dr. R. C. MUIRHEAD-THOMSON and Professors R. M. GORDON and T. H. DAVEY pleaded for standardization of experimental work on residual insecticides.

Dangers of Upsetting the Balance of Nature

Professor P. A. BUXTON opened the discussion, in which 22 speakers participated. He traced the development of D.D.T. from its origin in Switzerland, through preliminary experiments by Dr. Busvine at the London School of Hygiene and Tropical Medicine, and in America, to its large-scale production and use late in 1943. D.D.T. and the new insecticides had created a bigger change in medicine than had any chemotherapeutic substance. They had made possible the eradication of anopheline mosquitoes, the control of lice among ignorant people, and the abolition of phlebotomus, simulum, and ornithodoros species in certain areas. The sudden reduction in sickness and mortality thus produced was causing a rapid increase in population, with far-reaching results. The problems this caused would increase in geometric progression as these new generations reached reproductive age.

He then went on to discuss the paper by Professor Macdonald, which attempted to define the proportion of anopheles which must be killed (or kept from man) if control of malaria was to follow. It might be possible to get useful information on the age-structure of mosquito populations by marking mosquitoes with radioactive phosphorus. Of the new insecticides he said that a lethal effect in small doses was not in itself important, but extreme lasting power was very important. He was puzzled whether resistance to insecticides was genetic in origin or acquired. If the former, man had not created it, but had only discovered what had been there from the beginning. He protested against those who concluded from only field experiments that an insect was resistant to insecticides. Such people might be seeking to cover their idleness, or their results might be due to adulterated D.D.T. powder. Laboratory experiments were essential in this connexion. Professor Buxton concluded by pointing out that to standardize experimental field work on insecticides could be dangerous. Though one must control or measure natural variables, if possible, it was necessary to avoid limiting freedom of action in this type of work.

The appointment of Dr. Gérard Montus, of Marseilles, as deputy director of the W.H.O. regional office for Europe, located temporarily at Geneva, has been announced by Dr. Brock Chisholm. Dr. Montus has been on the staff of the World Health Organization since 1949, serving first as European regional adviser on maternal and child health and later as chief of the social and occupational health section, W.H.O. headquarters.

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Corneal Grafts

SIR,—The attention of Parliament has been called to consider an alteration in legislation so as to increase the supply of donor eyes by voluntary means for corneal graft surgery. In recent years, thanks to the French revival and improvement of an old method which is mainly free from complications, the scope and safety of corneal grafting have been increased and about 50% of suitable cases treated by this method show restoration of sight to varying degrees. The shortage of donor material is nation-wide and becomes steadily more so since it mainly depends to-day on the use of pathological eyes which have to be removed for disease not affecting the cornea: coincidentally the scope and applications of corneal graft surgery steadily expand.

Mr. B. W. Rycroft, who has been engaged in corneal graft surgery since 1936, has initiated a movement to obtain this alteration in the law and to ensure a legal and voluntary reservoir of adequate donor material. He should have the full support of our profession and he has my entire encouragement also in his endeavours to place British ophthalmology in the forefront of international practice in corneal grafting. It is true that our eye surgeons have been badly hampered hitherto in this type of work by war, lack of special instruments, untrained personnel, and inadequate donor supplies. But only the shortage of donors now restricts the expansion of graft surgery in this country, and it is to be hoped that Parliament will wisely amend the old Anatomy Act to solve this difficulty which obstructs modern eye surgery in the treatment of our fellow countrymen who are blind by corneal disease.—I am, etc.,

Cecil Wakeley.

Educating the Public about Cancer

SIR,—Drs. T. A. Watson and O. D. Beresford in their letter on educating the public about cancer (January 12, p. 107) tell of the "intensive publicity" in the U.S.A. and Canada, and more particularly in the province of Saskatchewan, where there has been "a marked increase in the percentage of early cancer seen in the Government clinics." However, that is only part of the story—a part that makes it imperative that more of it be presented. They might have told that, in spite of the publicity, propaganda, heavy financial outlays, and super-organization with increase thereby in the percentage of early cases, there was no reduction and no change in the trend of breast cancer age-specific mortality rates, but that these rates maintained fair levels, as they did, too, in each of the other provinces, some of which had no cancer control programme and no evident increase in the proportion of early cases receiving attention. (The book-keeping of all mortality for each of the provinces was done by the Dominion Bureau of Statistics.) They might have added that the level trends in the Canadian provinces were practically uniform with those in the State of Massachusetts, where there has been a long-established and very active programme of control, and were uniform also with the trends in England, where the complaint has been frequently made that propaganda and promotion for the control of cancer have been less than on this side. They might have concluded that whether or not early treatment can prevent the spread of the lethal metastases and thus prevent death in an occasional case of breast cancer, allowed as a possibility by Sir James Paget in 1853, the evidence to-day fully confirms Paget's view that early treatment cannot prevent death in more than that hypothetical occasional case, and, owing to the nature of breast cancer, cannot materially postpone death where it does not prevent it. (Of course,

Sedative and Therapeutic **TRISAN**★ Hommel in Bronchial **ASTHMA**

TRISAN—Hommel is an established agent in the symptomatic treatment of bronchial asthma and related states. It combines in its formula both sedative and anti-spasmodic drugs of recognized performance.

COMPOSITION Physicians experienced in asthma have long recognized the value of concurrent prescription of Potassium Iodide and Chloral Hydrate; a small dose of Soluble Barbitone is added as a sedative adjuvant to enhance their therapeutic effect. Trisan therefore comprises—

<i>Iodide of Potassium B.P.</i>	6.03%
<i>Chloral Hydrate B.P.</i>	7.11%
<i>Barbitone Sodium B.P.</i>	0.24%
<i>Alcohol</i>	4.00%
<i>Excipient ad</i>	100.00%

CLINICAL INVESTIGATION shows that Trisan produces spasmolysis and relief of expectoration in nocturnal asthma; its sedative component satisfactorily encourages sleep and provides an additional value in asthma complicated by hypertension.

INDICATIONS Trisan is indicated in bronchial asthma, especially nocturnal; certain types of hypertension; allergic diathesis. It is contra-indicated in iodine allergy and hyperthyroidism.

DOSAGE Four fl. drachms in $\frac{1}{2}$ tumblerful of fluid during attacks or before retiring; prophylactically: 1 to 2 fl. drachms nightly for 2 to 3 weeks.

PACKING Standard: Bottles of 4 fl. oz.; Dispensing: 16 fl. oz.

★ Trade Mark Reg'd.

121 NORWOOD ROAD, LONDON, S.E.24

NEW ADVANCE in sex hormone therapy

Mixogen is the new Organon preparation presenting the male and female hormones physiologically balanced in one tablet for the treatment of all signs and symptoms of declining sex hormone function in either sex.

The synergistic combination of these B.P. substances confers *beneficial results, greatly exceeding any obtainable with much larger doses of either of the components alone*, without the unwanted effects occasionally associated with one-sided sex hormone therapy.

The sense of renewed mental and physical vitality is a notable feature of the treatment.

The tablets are **FREELY**
PRESCRIBABLE UNDER
THE N.H.S.

"MIXOGEN" contains 0.0044 mg.
ethinylœstradiol B.P. and 3.6 mg.
methyltestosterone B.P. in each
tablet.

MIXOGEN

Male and Female Hormones in one tablet

In Perspex tubes of 25 tablets and in bottles of 100, 250 and 500.

Full Literature and Bibliography on request.

TEMPle Bar 0251-2

treatment can cure non-metastatic non-lethal breast "cancer," indistinguishable morphologically from lethal (metastasizing) breast cancer. However, cure of all such non-lethal lesions—which in consequence of educating the public (and the profession) about cancer have greatly increased among treated cases—would not reduce the cancer death rates.)

They might have told that, in spite of the programme in Saskatchewan and the shift to earlier cases, the age-specific mortality rates for female cancer as a whole for that province fail to show any reduction or any difference in trends from those of other provinces without control programmes. They could have added, too, that there was nothing in the Massachusetts rates any more than in the English rates to suggest that any appreciable control of cancer mortality as a whole had been achieved. They might have concluded that the evidence usually accepted as supporting the faith in early treatment is not unequivocal evidence, but that on the contrary the experience of the past 15 to 25 years shows indubitably that the great advantages claimed for early treatment "just do not exist in practice."

Indeed, the authors might have used the accumulated experience in demonstration of the abiding truth of Farr's words that "death is not deceived by sham defences." And they might well have quoted him further, that "false evidence injures instead of aiding the cause." As Dr. James F. Brailsford has so ably pointed out (November 10, 1951, p. 1154), there is nothing spectacular to offer and what there is had best be done quietly.

The evidence on which this note is based is summarized briefly in the February number of *Surgery, Gynecology, and Obstetrics*.—I am, etc.,

University of Toronto.

N. E. MCKINNON.

Penicillin Cream Dangerous?

SIR,—I read with interest Professor D. M. Dunlop and colleagues' analysis of National Health prescriptions (February 9, p. 292), and noted that 4% of prescriptions were for penicillin.

It is a pity that so much of this expensive drug should be wasted by its use in unsuitable cases and in ineffective doses, but it is still more regrettable that 40% of these prescriptions should be for penicillin cream. It may be that there are a few cases in which penicillin cream is indicated, but they must be very few, and in most cases parenteral penicillin would be far more effective and economical. For the vast majority of skin lesions, ulcers, and wounds penicillin cream is not only useless, but results all too often in the production of a resistance to the drug and, worse still, in severe sensitization.

In clinics for varicose veins and peripheral vascular disorders, where 1,000 or so cases are seen yearly, almost every patient who has had an ulcer, eczema, or infection of a toe from diabetic or other form of vascular deficiency has been given penicillin cream before he comes to the clinic. I can remember only two or three patients who felt the cream had done them any good; almost all discovered for themselves that the cream aggravated the lesion, and a great many developed severe, intractable, persistent, and often generalized skin eruptions.

I am convinced that penicillin cream, like sulphonamide ointment, has done far more harm than good, and it would be a benefit to the public, and to the Treasury, if its sale were prohibited.—I am, etc.,

Liverpool.

J. B. OLDHAM.

What Doctors Prescribe

SIR,—Referring to the article by Professor D. M. Dunlop and colleagues (February 9, p. 292) and subsequent correspondence (February 23, p. 435), there appear to be some points requiring emphasis:

Is there any special virtue in an extemporaneous pill, such as quoted over pil. cascara co. B.P.C. 1934? Formulae such as

those included in the B.P.C. and N.F. are usually the result of expert opinion, with rare exceptions such as aspirin mixtures.

With what frequency are the various N.F. preparations prescribed? Despite inclusion, there are preparations therein which are only rarely prescribed.

What is the position where a proprietary preparation and an official preparation cost the same? So far as I know the prescription of "sulphadimidine" does not lower the cost, apart from the other examples of insulin, etc., quoted.

The practitioner's right to prescribe must not be questioned, and the basic problem is to educate the doctor (if one may use this word) to the vast number of official preparations available. In this connexion certain points should be borne in mind:

"Academic" titles may be all right, but sometimes these strain the doctor's memory. Perhaps it is in a good cause to use the same ingenuity as the makers of branded goods and produce simple titles. For example, "Easton's syrup" is more easily remembered than the full official name.

When included in the N.F., B.P. and B.P.C. preparations should also have the formulae (%) included and not just the bare official name.

The N.F. should be made more comprehensive, and when a particular proprietary formula becomes extensively used the compilers should consider whether or not to insert a similar formula.

The same effective publicity, at the same cost, would be needed to achieve this as employed by the manufacturers of proprietary products. Merely sending the information to doctors is no guarantee that the matter would be thoroughly digested. Perhaps one of the cheapest ways in the end would be to supply every doctor with a free copy of *The Extra Pharmacopoeia*, when the new edition is published, which offers intriguing reading. Such an act does not, however, overcome the problem of keeping therapeutics up to date. How many doctors know the current view that the soluble sulphonamides, rather than the insoluble, are indicated in the early stages of dysentery?

Finally, before asking doctors to do anything, the Ministries should take care that their own house is in order. From time to time official publications, films, etc., use proprietary names for cotton and gauze tissue, collod. flex., and petroleum jelly.—I am, etc.,

Newcastle-upon-Tyne.

A. FORSTER.

SIR,—While acknowledging the great debt we owe to Professor Dunlop and his associates for the very painstaking and illuminating review of prescribing in the first few months of the Health Service (February 9, p. 292) I would like to point out the following two facts which have apparently been overlooked:

1. The form E.C.10A, though approved by the medical profession, has not been agreed to by the retail chemists and has never been implemented.

2. The fact that E.C.10A has never been in existence makes a number of the observations quite valueless, especially over sulphonamides and penicillin.

Their observation that inoculation for colds is not much good is not my experience after 20 years' experiment on myself and dozens of patients who return to me in the autumn year after year for fresh inoculation. The actual inoculation used may be one factor in this sphere.

I would like to add that, with all the statistical material now available quarterly, surely three years is a long time to take over a first instalment of what is obviously a very valuable field of research, both clinical, financial, and political. As many local executive councils have apparently been issued with this report and may be drawing their own conclusions, I feel that, the sooner their attention is drawn to the fact that some of these conclusions are inaccurate and misleading, the better they may be able to adjust their preconceptions.—I am, etc.,

Hadlow, Kent.

J. B. MARSHALL.

SIR,—Dr. Frewen Moor (February 23, p. 436) recommends the use of vaccine for the modification or prevention of severe catarrh, as he so graphically describes. My own

experience has been the same as his. If the successful use of vaccine in such cases is not reported, many will be discouraged by the large-scale experiments which have no bearing upon their selective employment.

Obviously where catarrh is caused solely by a virus bacterial vaccine can have no prophylactic value. But what I have noticed is not that vaccine-treated patients escape catarrh altogether—they do not: but they avoid severe and abnormally prolonged attacks such as they had previously been liable to incur, and even mild attacks become less frequent.

This is understandable if the catarrh virus is responsible only for the initial stages of an attack, prolonged exacerbations being caused by a latent bacterial factor coming into action when the virus has prepared the ground.

This latent bacterial infection may in turn keep the local level of resistance low to virus infection. Thus a vaccine which discourages the bacteria would tend to reduce the frequency as well as the severity of attacks.

—I am, etc.,

Leyburn, Yorks.

S. G. PEILL.

Cost of Treatment

SIR,—Your leading article on "Bacterial Resistance to Chemotherapy" (February 23, p. 425) is timely, and the opening sentence that "the clinical exploitation of a new antimicrobial drug passes usually through two main phases, the first being over-enthusiastic and somewhat indiscriminate, and the second more critical and restrained," bears repetition. In the same issue Drs. B. Wolman and A. Holzel (p. 419) describe the rapid response to "terramycin" of 34 young patients with pneumonia and 10 patients with upper respiratory tract infection. I suggest that their paper may illustrate the first phase of terramycin therapy, and before the second phase is reached there must be reports of further investigations backed up by control series.

There are, of course, patients suffering from respiratory infections who derive great benefit from chemotherapeutic agents, but many children respond to routine treatment without antibiotics equally rapidly and well. In a recent consecutive series of 24 children suffering from respiratory infections treated in the wards of the Liverpool University Department of Child Health at Alder Hey Children's Hospital, half the patients were treated with sulphonamide or penicillin, and the others (alternate patients) received no specific chemotherapy. The clinical response was similar in both groups, and in almost all patients the temperature had returned to normal within 24 hours. The time of disappearance of the radiological shadow was the same, and the average length of stay in hospital was 15½ days in each group.

Attention should also be directed to the economic aspect. The approximate cost of treating an infant weighing 15 lb. (6.8 kg.) for a five-day period, using the accepted dosage of chemotherapeutic agent, is 1s. with sulphamezathine, 3s. with crystalline penicillin, 9s. with "distaquine" fortified penicillin, 4s. 6d. with streptomycin, 23s. 6d. with chloramphenicol, 33s. with chloramphenicol palmitate, and 27s. 9d. with "aureomycin." Terramycin is not generally available in this country at the present time, but its cost will probably not be less than that of aureomycin.

It is obviously right that clinical trials of new preparations should be carried out, but the value of such trials is much increased when one or more control series is also studied.—I am, etc.,

Liverpool.

R. McL. TODD.

Cost of Anaesthetic Techniques

SIR,—While I agree with Dr. F. F. Waddy (February 16, p. 384) about the desirability of economy in the use of anaesthetic gases, I feel it important to emphasize the dangers of using minimal gas flows.

The technique he suggests, using a gas flow of 2 l./min. nitrous oxide and 0.4 l./min. oxygen in conjunction with a carbon dioxide absorber, casually viewed appears reasonable; but, assum-

ing a patient with a minute volume of 5 l. and an oxygen consumption of 200 ml./min., the mixture inhaled will contain less than 11% oxygen, scarcely a fit mixture on which to maintain a patient undergoing radical mastectomy.

Increase the oxygen supply by 0.2 l./min. and the proportions will be atmospheric; but, with such a small margin for error, what machine can be trusted sufficiently for one to dare use the optimum percentage?

I am afraid that the combination of human and mechanical fallibility renders this method too hazardous to the patient, who I am sure would prefer Dr. Bullough's "extravagance."—I am, etc.,

Manchester.

C. P. BROWN.

Hypnotism in Medicine

SIR,—Your recent correspondence on the use of hypnotism for the treatment of asthma has just come to my notice. The following case might be of interest to your readers.

An unmarried charwoman of 49 suffered from asthma since the age of 13. Recently the attacks had been growing more frequent, each attack being of longer duration than the preceding. Two months ago she passed into status asthmaticus, which she had done on previous occasions. This time, however, the attack refused to yield to orthodox—i.e., adrenaline and aminophylline—therapy in the ward of a large general hospital. After remaining in this condition for 10 days it was feared that cardiac failure might supervene, and she was referred to me.

The patient was hypnotized and told that the asthmatic attack would stop immediately; within a few seconds the rhonchi, which could be heard with ease many yards away, disappeared and the patient's comfort and colour improved. After five minutes of repeated suggestion that the wheezing would go and expiration would become less difficult the attack had completely terminated.

It is of interest to learn that up to the time of writing the patient is free of attacks and has been discharged from the hospital. Previously she had had at least one attack per day for the last five years.

It would seem that, when all other methods of treatment fail, before resorting to cortisone an attempt at relief by hypnotic suggestion might be made. The least that can be claimed for it is that it is a great deal cheaper.

For those concerned with the psychological aspect of asthma the history of the case is of interest. The onset of this patient's asthma coincided with her removal with her seven sisters from their home to a convent. The mother was permanently deprived of the custody of the children and the father sent to prison for incestuous relationship with his daughters, the patient included. The ages of the girls ranged from 10 to 19, and they had been submitted to this relationship since the age of about 5. One other sister developed asthma at precisely the same time as the patient.—I am, etc.,

East Grinstead.

A. A. MASON.

L-Noradrenaline as Vasoconstrictor

SIR,—The use of L-noradrenaline for the treatment of hypotensive states has recently received considerable attention (Dr. H. C. Churchill-Davidson, December 29, 1951, p. 1551). Dr. R. Ghose (February 16, p. 385) recommends intravenous infusions lasting up to 48 hours. Although our experimental work is incomplete our recent findings compel us to draw attention to certain possible dangers in these procedures.

In man intravenous adrenaline increases liver blood flow, noradrenaline decreases it (Bearn *et al.*, *J. Physiol.*, 1951, **115**, 430). Our own experiments in animals have shown that in a long-continued infusion the dilator action of adrenaline (which is in fact reflex in nature, a response to the raised blood pressure) is superseded by a progressive diminution in blood flow. This effect is even more marked in the case of noradrenaline, the direct action of both drugs on the liver blood vessels being thus vasoconstrictor. Moreover, our evidence demonstrates that noradrenaline and adrenaline both have a marked constrictor effect on the terminals of the hepatic artery, a point of significance, as the main oxygen supply of the liver is through these channels.

There are important implications in these observations. The organs normally used by nature in the regulation of peripheral

resistance are structures such as the skin and bowel, whose vascular needs may be important but are rarely urgent. Our observations indicate that liver blood flow is a function aloof from such petty adjustments. Changes in blood pressure produce only transitory effects, and surprisingly high levels of flow are maintained even in the presence of low systemic blood pressures. The primary object of blood-pressure regulation is, after all, to maintain an adequate blood flow through vital organs. There are few organs more vital than the liver. There are few organs more readily damaged by an inadequate supply of oxygenated arterial blood (E. J. Delorme, *Lancet*, 1951, 1, 259). To preserve blood pressure by subjecting the liver to long periods of relative ischaemia would seem to be a hazardous and unphysiological procedure—particularly if it has already been exposed to possible harm from varying periods of hypotension.

It might not have been thought necessary to bring these points forward were it not already known that long periods of adrenaline infusion result in severe and irreversible liver damage (F. A. Bainbridge and J. N. Trevan, *British Medical Journal*, 1917, 1, 381). The evidence we have mentioned shows that with respect to the liver *noradrenaline* has vascular effects similar to, though even greater than, those of adrenaline. There is no suggestion that brief infusions might be harmful, but it is our view that *noradrenaline* administration for periods longer than an hour or so is a potentially dangerous procedure which might merit further investigation before its general adoption.—We are, etc.,

Departments of Physiology and Pathology,
University of Bristol.

J. GRAYSON.
D. H. JOHNSON.

SIR,—Dr. H. C. Churchill-Davidson (December 29, 1951, p. 1551) mentions the use of *L-noradrenaline* for the treatment of collapse under spinal analgesia. This drug has been found most useful in the prevention—rather than the treatment—of blood-pressure falls under spinal analgesia. With a few modifications the spinal technique described by R. Marcus and T. C. Gray (*Brit. J. Anaesth.*, 1949, 21, 182) has been used in this centre for some time for Wilson Hey prostatectomy, the blood pressure being maintained at the pre-operative level by 1:250,000 adrenaline drip. In recent months *L-noradrenaline* has been substituted for the adrenaline. The series is not yet big enough to make a statistical evaluation of this innovation, but the following clinical impressions have been formed of the differences between *L-noradrenaline* and adrenaline.

With *L-noradrenaline* much less solution is required to maintain blood pressure. In several cases when only 10–20 drops per minute were required it was considered advisable to change to 1:500,000 solution in order to give adequate control of the pressure.

The drip can be discontinued sooner with *L-noradrenaline* than with adrenaline without any fall in blood pressure. With the latter it was not unusual to find that the infusion had to be continued for 12 or more hours. In 65% of the cases in which *L-noradrenaline* was used the drip was discontinued in the theatre; and in the remainder the longest time it was required to be continued in the ward was four hours.

The tachycardia of adrenaline was replaced by bradycardia. Pulse rates observed were mostly between 55 and 68 per minute. Blood-pressure changes do not occur so quickly with *L-noradrenaline* as with adrenaline.

Despite the theoretical objection that *L-noradrenaline* produces vasoconstriction of the renal vessels (H. C. Churchill-Davidson and others, *Lancet*, 1951, 2, 803) no cases of post-operative anuria have occurred. The convalescence of this series of cases has not differed from those in whom adrenaline was used. In a few cases E.C.G. tracings were taken before, during, and after the use of *L-noradrenaline* and no abnormalities have been noted.

On one point the findings are at variance with those of Churchill-Davidson—namely, the diastolic pressure was not always maintained as well as the systolic. In about half the cases there has been an increase of 5–15 mm. mercury in the pulse pressure, but in the remainder this was unaltered or slightly decreased.—I am, etc.,

Liverpool.

JOHN W. DUNDEE.

Frequency of Micturition

SIR,—Mr. H. P. Winsbury-White in his article on this subject (February 16, p. 372) makes special reference to children and to enuresis in which, as we all know, a frequency but less commonly an urgency of micturition occurs. His remarks upon cerebral impulses, emotional disturbances, and the effect of profound sleep are readily conceded, but his main theme is upon those chronic inflammatory processes which can occur in the posterior urethra and upon other physically abnormal findings.

The question which perturbs me is whether or not one should, as a necessary part of the physical examination of these children, submit them to a routine urethroscopy and cystoscopy. A long experience of enuresis in consulting and clinic practice, and in the taking of some of these cases into my private home where they have been watched by day and by night, suggests that one is not justified in doing this unless all methods of approach to the child and his home, together with every possible attack upon the condition itself, have met with absolute failure in which there is no improvement of any kind, however transitory. Such matters as residual urine, meatitis, adherent prepuce, vulvitis, and cystitis can be readily recognized, though their successful treatment does not necessarily, and in my opinion not usually, bring relief to the enuresis. Tonsillectomy has at times "cured" enuresis, as has circumcision, but this is not because the child has lost a conceivably diseased or unduly hypertrophied tonsil or a long and tight foreskin; such conditions are more rightly regarded as coincident and not causal, and this probably holds good in the rare instance of spina bifida occulta. But the presence of granulomata or polypi in the posterior urethra, or of a localized or generalized urethral contraction, is of a very different order and might well be regarded as causal, and all the psychotherapy in the world will be as so much wasted time and effort if the child is all the while suffering from something of this kind, which, tragically, has been missed because it just was not considered in diagnosis.

It may well be that some of that hard core—as it has been called—of enuretic children who show no response to any form of treatment are suffering from the conditions which Mr. Winsbury-White has described; and, if this is so, his article can scarcely be overestimated in value.—I am, etc.,

London, W.1.

MAURICE L. YOUNG.

Prostatic Obstruction and Inguinal Hernia

SIR,—Of the many benefits conferred on the elderly patient by modern closed methods of prostatectomy not the least is the great reduction in the incidence of post-operative incisional herniae. In contrast to this was the bulge which developed at the site of the tube track in nearly 50% of the patients after open prostatectomy and necessitated the wearing of a belt, often in addition to the apparatus already worn to control an inguinal hernia.

In many patients divarication of the recti will follow a vertical incision of the linea alba whether the bladder has been drained or not, and this is always a source of increasing weakness to the abdominal wall. For this reason a transverse suprapubic incision as recommended by Mr. Thomas Moore (February 16, p. 362) is becoming increasingly popular among urologists, and the supra-symphysial Pfannenstiel scar is now no longer to be regarded as the exclusive property of showgirls and artists' models. Ever since I was converted to this incision some years ago I have not ceased to marvel at its efficacy—in fact, the thin and flabby type of abdominal wall sometimes appears to have been even strengthened, and on more than one occasion I have observed the disappearance of a small direct bulge subsequent to operation.

Mr. Thomas Moore's concern over the problem of an obstructing prostate complicated by an inguinal hernia is shared by all urologists, and recent reports both in this country and in America make it clear that it is becoming an increasingly common practice for both conditions to be dealt with simultaneously by open operation whenever conditions permit. Personally I believe that simple removal of an indirect hernial sac is all that should be attempted in these cases, and for this purpose the abdominal extraperitoneal approach to the inguinal (or femoral) canal as described by Henry (*Lancet*, 1936, 1, 531) is ideal. Removal of the sac by this method is usually surprisingly easy, but when it is adherent gentle traction on the testicle in the scrotum by an assistant, as recommended by Henry, facilitates the dissection. After removal of the sac a patulous internal ring should be

narrowed by an occluding suture to prevent recurrence, care being taken not to damage the vas as it enters the internal ring postero-mesially or the internal spermatic vessels postero-laterally. Irreducible herniae, of course, can be dealt with only through a separate scrotal incision, and in these cases a very adherent sac can be left *in situ* after its contents have been freed and returned to the abdomen, the neck of the sac being occluded by a ligature from the abdominal aspect.

I believe that the extra time spent on an elaborate repair of the inguinal canal, especially when the hernia is a direct one, is quite unjustifiable in this class of patient, and furthermore, even though the dangers of post-operative extravasation of urine are admittedly slight with modern closed methods, the development of a wound infection in this area from such a cause would be a serious complication, and one which might well develop into a major disaster.—I am, etc.,

London, W.1.

JOHN SANDREY.

SIR,—I read Mr. Thomas Moore's article on prostatectomy and herniorrhaphy (February 16, p. 362) with interest, as for some time I have been using a similar procedure. Though the end-result is much the same, the method is different, and I think, therefore, it may be worth while describing it. Since Professor A. K. Henry first described his method of extra-peritoneal approach in the repair of femoral hernia I have used it almost exclusively for all types of femoral hernia though not for inguinal hernia, although it had been described by Cheatle many years before for inguinal hernia.

Of recent years, using a transverse incision for prostatectomy—almost always the vesico-capsular (Ogier Ward) operation—I have also removed any hernial sacs extra-peritoneally. After the prostatectomy is completed my assistant retracts the rectus on the side of the hernia and by a process of traction on the peritoneum and gauze dissection the neck of the sac comes into view. Once the neck is isolated it only requires a little patience and gentle blind dissection by a finger in the canal to produce the entire sac. This is then divided at its junction with the peritoneum of the abdominal cavity and the opening either ligated or sutured like any other opening in the peritoneum. I have not found it necessary to do any repair to the canal.

Whether or not I have removed a hernial sac, it is my practice also to ligate the vas where it passes over the pelvic brim, as I have found that occasionally there is a little reaction and discomfort in the wound when the vas is approached and ligated through the usual separate incision near the root of the scrotum.

—I am, etc.,

Hartlepool.

H. M. GRANT.

Experiment in Peacemaking

SIR,—It is generally accepted that when a situation is desperate anybody, however obscure, is justified in submitting a plan of action—provided always that he has something original to propose and that it is the outcome of hard thinking. It was strictly on that basis that I proposed (*Journal*, December 1, 1951, p. 1337) that our Association should undertake an experiment in peacemaking. I would be grateful if I might be allowed to outline the argument on which my proposal was based.

It seemed to me that the threat of another world war concerned the medical profession in two ways: the state of the public mind, and our responsibilities in the matter of the prevention of war. I felt that it was high time that the problem was tackled as a scientific problem—and very largely a medical problem—in which research and experiment were more than usually important; that consultation and co-operation with other professions were required, and that it was essential that this problem should be dealt with quite regardless of political, or even religious, opinions.

First there is the fact that the public have suffered so much from the consequences and the threat of war that they are sick in mind and sick at heart. It is not possible in a letter to do more than indicate what troubles them. An example of what bewilders them is a policy which does away with all the air-raid shelters and at the very same time talks of plans to deal with a million casualties in one place in one night. Next, they are horrified by the ever-increasing cruelty and ruthlessness of never-ending war. They are tormented by questions such as what would happen if an enemy were to announce that all captured

airmen would be tortured to death—not at all an unlikely announcement. Another anxiety is the extension of the policy of "frightfulness." It gets worse and worse and seems to be taken for granted. Take, for example, the problem of enlisting women in the Forces. In the first world war all the most influential women took up nursing, but in the second world war nearly all of them volunteered for the Forces. These are examples of questions that are weighing on the public mind, and there is great danger that morale may be worn by anxiety and hope deferred down to breaking point.

For this reason, if for no other, we must face the question of our responsibility in the prevention of war. I would not suggest for a moment that the B.M.A. should take any part in politics: what I do suggest is that we have no right to say that the prevention of war is a matter for the Government and no concern of ours. The right view, I am sure, is that it is extremely unlikely that any government can prevent war unless organizations such as the B.M.A. do take their part in making peace in their own field.

I would suggest that a reasonable view of the Russian problem is this: The foreign policy of the Kremlin is extremely obscure, one of the great difficulties being that so many of their speeches are almost unintelligible. The great fear is that they may be scheming to make the whole world Communist, if necessary by force—perhaps with the idea that this is the only way to prevent wars. However that may be, it is obvious enough that the present Russian Government is almost impossible to deal with. Negotiations drag on interminably, and the bills for armaments keep mounting up. We may be bankrupt long before we reach any settlement with the Kremlin.

But if we turn from the Russian Government to the Russian people the outlook is very different. There does not seem to be any difficulty in understanding the ordinary people; they seem to be very much like ourselves and quite different from the Nazis. There is nothing to show that they want to make the whole world Communist, certainly not by force. All the evidence is that they are very willing to live and let live. There seems to be no reason at all why the ordinary people on the two sides, if they could get to know each other, should not make friends. It is clear enough that in the end the only way to prevent war is to make peace day by day, year by year, and my suggestion is that that is the province not of the Government but of the people themselves. I would say that it is the function of the Government to defend the peace until the ordinary people have made it clear that armaments are no longer needed. The cold war, with all its hideous risks, will go on until the ordinary people make peace.

Our concern is that the ordinary man in the street can do nothing at all on his own, but in these days people are organized in all sorts of ways and can get into touch with their opposite numbers in other countries through their professional, business, and trade associations. And that is where our own responsibility lies. Just as each of us has a dual responsibility, as a doctor and as a citizen, the responsibilities of the B.M.A. extend beyond the field of pure medicine in this country. Nearly a hundred years ago Sir James Paget addressed the students of St. Bartholomew's Hospital on two or three occasions on the subject of their responsibilities. He was one of an illustrious line and he voiced a tradition going back in one hospital for nearly a thousand years. It is impossible to believe that what he said can apply only to our own patients or our own country. His teaching was that our responsibilities "are as various as are the ills that flesh is heir to; they are as deep as the earnestness with which men long to be delivered from suffering, or from the grasp of death." We are bound "by the weightiest responsibility to God and man. . . ."

—I am, etc.,

Wetherby, Yorks.

R. L. KITCHING.

Debauchery of Honest Words

SIR,—Kindly allow me to express a strong protest against the admission to the *British Medical Journal* of the phrase "spectrum of antibacterial activity" in the summary of the article on "terramycin" by Drs. B. Wolman and A. Holzel (February 23, p. 419). The word "spectrum" means an image—usually that formed by rays of light—in which the parts are arranged in a progressive series according to their refrangibility (*O.E.D.*), and how an image can have antibacterial activity should be explained by those who perpetrate the usage I complain of.

It was once said of the word "allergy" that it had become so debauched by misuse that it would be fortunate if it could be dropped from the vocabulary of scientific

Extract *from an Annotation in the British Medical Journal*
of January 5, 1952:

"The recent trial published* by the Medical Research Council subcommittee showed clearly that penicillin was at least as effective as aureomycin or chloramphenicol in the treatment of bacterial pneumonia—and very much cheaper. . . . Because it produces the most rapid response, the authors [of a report† of a trial at Philadelphia General Hospital] believe that it is best used even in cases where the pneumonia is not certainly bacterial but may be viral, since it is bacterial pneumonia which has the high mortality."

A new preparation of

Aspirin

for

Children

A SAFE AND ACCURATE DOSE OF ASPIRIN—There is little fear of an anxious mother giving too large a dose of Angiers Junior Aspirin for Children. Each tablet contains $1\frac{1}{2}$ grains of Aspirin.

IN AN EASY TO TAKE TABLET—The pleasant orange flavour and sweetening in this small pink tablet makes Angiers Junior Aspirin acceptable to children even if sucked or chewed.

WITH A SAFEGUARD AGAINST GASTRIC IRRITATION—The combination of di-calcium phosphate with the aspirin guards against any irritation caused by the acid effect of the aspirin.

Acid. Acetylsalicylic. 1.25 grains. Di-Calcium Phosphate 1.50 grains; sweetening and orange flavouring to taste.

Bottles of 50 tablets 1/6

ANGIERS JUNIOR ASPIRIN

for children

A Product of

THE ANGIER CHEMICAL COMPANY LIMITED,
86, CLERKENWELL ROAD, LONDON, E.C.1.

Laboratories—Ruislip, Middlesex.

Notes on High-Protein Diets

(1)

PROTEIN TREATMENT OF OBESITY

In the treatment of obesity by dietary correction the intake of calories should be limited to between 1,000 and 1,200 calories a day, and the patient should be supplied with optimum quantities of protein, vitamins and minerals. Thus the patient is forced to live for a time on his own fat resources and weight falls.

THE MOST PRACTICAL METHOD TODAY

At least 65 grams of protein should be given daily in order to ensure replacement of that lost by daily catabolic processes and to enable the patient to burn his own fat. In addition, protein has a high-specific dynamic action and a role in thyroid function.

Owing to the rather meagre dietary allowance available today, the most practical method of guaranteeing this daily amount of protein is to add Sanatogen protein supplement to the patient's diet. Sanatogen contains 95% casein combined with 5% sodium glycerophosphate and has a specific nutrient and tonic action. It supplies all the essential amino acids together, has a high rate of utilisation, and is easily digested and rapidly absorbed.

Sanatogen is the only proprietary protein supplement containing neither fats nor carbohydrate. The fact that animal protein is normally closely associated with fat enhances the value of fat-free Sanatogen in obesity diets.

EQUAL TO 6 OZ. LEAN BEEF DAILY

Taken three times daily, Sanatogen provides the patient with the equivalent protein nourishment of 6 oz. of lean beef. It is very easily administered. Normally taken mixed as a hot or cold drink, Sanatogen can also be sprinkled on food or mixed in cooked dishes. The routine addition of Sanatogen to the patient's diet in this manner is the most practical solution to the difficult problem of maintaining a high-protein intake today.

Practitioners who wish to carry out their own clinical tests will be given every help. Please write to the Medical Department, Genatosan Ltd., Loughborough, Leicestershire, for further information and medical samples.

SANATOGEN *for high-protein diets*

The word 'Sanatogen' is a registered trade mark of Genatosan Ltd., Loughborough, Leics.

language, and now it is the turn of "spectrum" to be ill-treated.

I ask for your powerful editorial aid against this debauchery of honest words.—I am, etc.,

Belfast.

H. G. CALWELL.

Appeal for Specimens

SIR,—The Medical Research Council's Dental Research Unit is in urgent need of certain post-mortem material for its investigations into dental and associated disease. In particular, the jaws, or parts of jaws, with teeth *in situ*, are required from healthy mouths; from cases with gingivitis but no other specific lesions; from cases of ulcerative stomatitis; and from epileptics formerly under "eupanutin" (sodium diphenyl hydantoinate) control. When any of this material is or is likely to become available it is requested that this unit be notified (Telephone: Brixton 4744). Arrangements will then be made to collect the specimens, which if possible should be removed and fixed in 10% formalin soon after death.—I am, etc.,

Medical Research Council,
Dental Research Unit,
King's College Hospital Medical School,
Denmark Hill, London, S.E.5.

J. J. D. KING,
Director of Unit.

POINTS FROM LETTERS

Overwhelming Response

Miss D. J. COLLIHOLE (Director, Periodicals Department, British Council) writes: We think that your readers may like to know that as a result of the overwhelming response to the appeal for used copies of medical journals (which was published in the *British Medical Journal*, November 24, p. 1291, after a suggestion made by Sir Clement Price Thomas following his visit to Yugoslavia) the total number of medical periodicals already forwarded to Belgrade is about 4,600. Our representative, in acknowledging them, writes that Dr. Djukanovic, the Yugoslav Deputy Minister of Health, upon being informed of this valuable gift, immediately sent two members of the committee dealing with the distribution of medical periodicals in Yugoslavia to examine the consignment. The two doctors were clearly delighted by the sight of so many much-needed British journals and at once agreed to arrange for their distribution throughout the country, promising that priority should be given to professors of university medical and surgical clinics, as suggested by Sir Clement Price Thomas, and that hospitals and surgeons whom Sir Clement visited during his recent operating tour should also be included in the distribution. Because of the large number of journals received, it has been impossible to acknowledge them all individually, and we should be most grateful if you would convey our thanks to the many donors through the columns of the *British Medical Journal*.

Frequency

Dr. R. A. P. CORKERY (West Drayton) writes: . . . I was brought up in perhaps a pedantic school of medicine and was always taught that "frequency of micturition" is normal and healthy, but that "increased frequency" is not. Surely, Sir, anything that occurs periodically can be termed "frequent," and can still be within normal limits. We can talk of frequency of meals, frequency of surgeries, frequency of holidays—they become abnormal only when this normal frequency is altered. If the term "frequency" is construed as I think it should be . . . the only cause of frequency of micturition is the presence of a sufficiency of fluid in the bladder.

Staining of Brain Tumours

Dr. I. EBAN (London, W.1) writes: In your annotation on "Locating Brain Tumours with Isotopes" (February 23, p. 428), 1948 is the earliest date which you give in connexion with the staining of brain tumours by intravenous injection of a suitable dye. For the sake of historical accuracy I would like to point out that as far back as 1931 brain staining was already being done by Friedemann and Elkeles. This fact is mentioned with some detail in the *Proceedings of the Royal Society of Medicine* for January, 1943 (pp. 137-140).

Correction

In the account of the life of the late King, which was published in the *Journal* of February 16 (p. 386), the name of Sir Morton Smart, G.C.V.O., D.S.O., M.D., was omitted, through an error which we much regret, from the signatories of the bulletin (issued on November 23, 1948) announcing that the King was suffering from obstruction to the arterial circulation of the legs.

Obituary

A. R. PARSONS, M.D., F.R.C.P.I.

Alfred Robert Parsons, who died at his home in Dublin on January 24, was born in 1864, and after a brilliant career at Trinity College, Dublin, graduated M.B., B.Ch. in 1888. He won the medical scholarship and medical travelling prize, and continued his studies in Vienna and Berlin. In 1894 he was appointed visiting physician to the Royal City of Dublin Hospital, a position he held till his death, and rapidly became one of the leading physicians in Dublin and an outstanding clinical teacher. In 1894 also he was elected a Fellow of the Royal College of Physicians of Ireland, of which he was senior Fellow for many years.

Throughout the years his mind remained as keen and as active as ever, and his bodily vigour showed little sign of impairment. He never retired, but continued his full hospital work to the end, taking his usual clinical class the week before he died. For 58 years he was a fascinating clinical teacher, one who could hold the attention of students and stimulate their interest. He taught them to observe accurately, to examine a patient carefully and critically, to evaluate what was found, and to be self-reliant, but not cocksure, in judgment. A diagnosis was held in almost tantalizing suspense until all the facts on which it was based had been thoroughly worked out. Parsons saw many changes in medicine, but his reliance on symptoms and, above all, on physical signs as the sure foundation for diagnosis did not change. Although pathology, bacteriology, serology, radiology, biochemistry, and all the other present-day aids to diagnosis were used by him fully, he was not carried away by any uncritical enthusiasm for what was new. In treatment he showed no hesitation in abandoning the elegant potions and pills of the 'nineties in favour of the synthetic chemicals and antibiotics of to-day, and was always eager to use a new remedy, though he tried out each one carefully and experimentally before passing judgment upon it.

During the first world war Parsons served in the R.A.M.C. He was on the staff of 83 General Hospital in France with the rank of lieutenant-colonel.

Parsons took a keen interest in scientific medical meetings. He was an original member of the Association of Physicians of Great Britain and Ireland, and was a past president of the Royal Academy of Medicine in Ireland, and a member of the "Bi" Club. It was a great pleasure to hear him read a paper or to see him demonstrate a rare clinical case. The thorough investigations, the scientific clarity, and the dramatic presentation were all admirable.

Dublin has lost its oldest and most beloved clinical teacher. He was a steadfast and loyal colleague, a skilful and warm-hearted physician, a courteous and modest man. His sense of duty, his tenacity of purpose, and his rigid moral values remained unchanged throughout his life. Thousands of his former students in all parts of the world will always remember "Alfie" Parsons with gratitude, affection, and veneration.—V. M. S.

Sir DOUGLAS SHIELDS, M.D., F.R.A.C.S.

Sir Douglas Shields, who began his career as a surgeon in Australia and later built up a big practice in London, died at Merstham, Surrey, on February 22, aged 73.

Douglas Andrew Shields was born in Melbourne on July 21, 1878. His father was a much-respected Scottish doctor holding an administrative position in that city. Douglas Shields studied medicine at Melbourne University, to which he won a scholarship and where he was first among those who obtained first-class final honours. He graduated M.B., Ch.B. in 1897 and proceeded M.D. in 1901. For a time he practised in a country district, but soon returned to Melbourne on his appointment to the staff of St. Vincent's Hospital, where he became a senior surgeon. Shortly after his return from a trip to London he was appointed consulting surgeon to the Governor-General of Australia (at that time the Earl of Dudley).

Two or three years before the first world war Shields decided to leave Australia and settle in London, where he established a private hospital in Park Lane. During the war this hospital was given up to the treatment of wounded officers. For a time he worked as a surgeon at a hospital in Wimereux in France. He was knighted for his wartime services in 1919, and three years later given the honorary degree of LL.D. at St. Andrew's University during the Rectorship of J. M. Barrie. After the war Shields's surgical practice continued to expand, and for a time he worked in association with Sir Alfred Fripp. His attractive personality and good appearance made him a much-sought-after man. His professional reputation was well deserved, for he was a neat and careful operator and kind and attentive to his patients.

Sir Douglas Shields married Mary Ellen, daughter of the late Charles Shirrefs, in 1900. His wife died in 1939, and he is survived by a son, who is also a medical man.

Dr. ARCHIBALD MACEWAN died on January 31, after a brief illness, aged 51. A native of Lochgilphead, Dr. MacEwan was born on October 2, 1900, and was educated at the University of Glasgow, where he graduated M.B., Ch.B. in 1925. In the same year he joined his cousin, the late Dr. John A. Thomson, in general practice at Hamilton, where he practised until his death. He was on the Crown list of medical examiners, and on many occasions gave evidence in the High Court and Sheriff courts, where he was regarded by Bench and Bar as a scrupulously fair expert. He was appointed a medical referee for the Sheriffdom of Lanark in 1945, and, until the abolition of the Poor Law system in 1948, when the National Assistance Act was placed on the Statute Book, was a certifying officer under the Lunacy Acts. During the war he was keenly interested in civil defence, and gave much of his leisure time to the training of first-aid and ambulance units. A quiet, kindly man who inspired confidence in his patients, he will be sadly missed by them and by his many friends. He is survived by his wife and son.—A. N. D.

The death on February 16 of Dr. J. W. LOGIE removed a general practitioner of the old school and one of distinguished ability. Born in 1869 of Orcadian stock, John William Logie was educated at Glasgow High School and at the University of Glasgow, where he had a notable career as a student. He graduated M.B., C.M., with high commendation, in 1891, and, after serving as a resident house-surgeon at the Victoria Infirmary and as resident assistant physician at the Belvidere Fever Hospital, Glasgow, he was for some years in practice in Partick. A period at sea, as a ship surgeon, followed for health reasons. He resumed general practice first at Pontyclun, Glamorgan-shire, and then at Rothes, in Morayshire. During the war of 1914-18, he was in charge of the Red Cross Hospital at Pontyclun, receiving Queen Alexandra's Medal for his

services. Failing health in the early 1930s led to his retirement to Aberdeen, where during the last war he served regularly on medical boards. Throughout his retirement Dr. Logie retained an alertness of mind and crispness of phrase, both of which gave great pleasure to his many friends, professional and lay. Proud of his profession, though critical of some recent changes, he maintained contact to the last with current developments in medicine. His insight and robust good sense, informed by wide experience as a practitioner, were greatly valued by younger colleagues. In August last Dr. and Mrs. Logie celebrated their golden wedding. He is survived by his widow, a son, Mr. Norman J. Logie, the Aberdeen surgeon, and a daughter, who is the wife of Dr. George I. Davidson, of Aberdeen.—R. M. N.

Dr. ALFRED HOWARD PARKINSON died at Wolverhampton on February 16, aged 76. After a childhood spent partly in France he began his working life as a teacher of science in Knaresborough, Yorkshire. He took the London B.Sc., with honours, in 1901, and then his interest turned to medicine, and he graduated M.B., B.S. in 1906, taking the Cambridge D.P.H. in 1909 and proceeding M.D. in 1911. After periods in Leeds and in the east end of London he was appointed by the newly constituted Staffordshire, Wolverhampton, and Dudley Joint Board for Tuberculosis to be tuberculosis officer to the Stafford area, which included Groundsley Sanatorium, at Tittensor, Stoke-on-Trent. Except during his service in the R.A.M.C. in the war of 1914-18, he continued to act in this capacity until March, 1947. His work was his whole life, and after his retirement he kept himself fully employed by acting as locum-tenent for many colleagues in Staffordshire. He was an indefatigable worker and could not be persuaded to take life easily. His mind was so alert and his interest so keen that during the past few years he frequently expressed regret that he could not begin all over again now that so many advances had been made in the treatment of pulmonary tuberculosis. Dr. Parkinson was a past president of the Midland Tuberculosis Society, and in his presidential address a few years ago he reviewed the many changes in treatment which had occurred in his lifetime. During these long years of service his wide clinical knowledge was willingly given for the assistance of patients and colleagues, and it was rendered the more valuable by his unfailing courtesy and kindness. His generous human sympathy was particularly helpful in the type of work he had chosen. He was held in affectionate esteem by his colleagues in Staffordshire, with many of whom his association had been very close. Many patients will mourn his passing, for he was indeed a good physician. He had continued at work until three weeks before his death, and gave in only when illness compelled him to do so. He is survived by one married daughter.—G. R.

Lieutenant-Colonel F. M. GRAHAM, late I.M.S., who died in Manchester on February 17, after a short illness, was born in Bangalore, Southern India, on March 8, 1892, the eldest son of William S. and Florence E. Graham. Frederick Montague Graham received his medical education at Madras Medical College, and took his diploma in 1914. He saw active service in the Middle East during the war of 1914-18, being twice mentioned in dispatches, and he served also in Afghanistan in 1919 and in the Calicut riots of 1921. In 1922 he continued his medical studies at King's College Hospital, London, taking the M.R.C.S., L.R.C.P. in 1924. He returned to India in that year and joined the civil medical service of Madras, where he was lecturer in surgery and medical jurisprudence at Stanley Medical College from 1924 to 1929. Later he held hospital appointments in Madras Presidency, and he joined the staff of Government House, Madras, in 1934. In 1944 he was recalled to active service in the Middle East Paiforce (Persia, Afghanistan, Iraq), in which he served throughout the last war. He retired from the I.M.S. in 1947.

For smooth gentle control of constipation

Agarol*, an emulsion of mineral oil and agar-agar with phenolphthalein, provides a treatment designed to re-establish the correct pattern where bowel evacuation is deranged. The phenolphthalein in Agarol provides gentle threshold stimulation; the hydrophilic properties ensure a moist yet well formed stool; the agar-agar content supplements mucin deficiency; the highly emulsified mineral oil mixes readily with the intestinal contents to form a soft lubricated mass. The palatability of Agarol makes it acceptable to the most fastidious patient.

INDICATIONS For chronic constipation and intestinal auto-intoxication. For restoring sluggish bowel activity to normal regularity in the elderly. For expectant or nursing mothers. To obviate straining in patients with high blood pressure, tuberculosis or heart disease. To provide lubrication where hæmorrhoids or other painful anal conditions are present.

*Paraff. Liq. 31.75%, Phenolphthal. 1.32%,
Agar-agar 0.21%, Excipients, etc., to 100.*

Sulphonamide
Suspension*

MEGALOBlastic ANAEMIAS

Marmite has been proved to produce a response in certain forms of megaloblastic anaemia, such as nutritional macrocytic anaemia, the anaemias of coeliac disease, idiopathic steatorrhoea and sprue, and in megaloblastic anaemia of pregnancy.

The mechanism by which Marmite acts is still unknown. It has been suggested that the folic acid in Marmite may be responsible; a more recent suggestion is that Marmite may contain folinic acid.

ENERGEN DIETARY SERVICE
(Dept. A.54)

65 Pound Lane Willesden N.W.10

A colleague writes: In January, 1949, Graham was appointed a medical officer of the Ministry of Pensions, and, though he was to hold the post only some three years, his quiet ways and endearing qualities made a particular impression on his colleagues, and his loss is most keenly felt. He was quite selfless and had a strong and abiding religious faith. Lieutenant-Colonel Graham is survived by his widow, a son, and a daughter. His son is demonstrator in pathology at King's College Hospital and his daughter is training as a radiologist at the Manchester Royal Infirmary. The sympathy of his many friends, professional and lay, is extended to them in their grievous loss.

Cumberland has lost a wise and skilful surgeon by the death, on February 21, of Mr. GORDON NEILL at the early age of 34. Andrew Gordon Currie Neill did well at Sedburgh School and at the University of Edinburgh, where he graduated M.B., Ch.B., with honours, in 1941. After serving as house-surgeon and house-physician at Cumberland Infirmary, Carlisle, he became resident surgical officer at Hull Royal Infirmary. He was elected F.R.C.S.Ed. in 1943 and returned to Cumberland Infirmary as resident surgical officer, becoming honorary assistant surgeon in 1947. Early in his professional career Neill came under the influence and guidance of Mr. J. N. J. Hartley, and was at an unusually early age a surgeon of wide experience, mature judgment, and quite exceptional technical achievement. A modest manner lightly cloaked an inner strength which gave his patients confidence, so that they became his friends. He accomplished a vast amount of work, but never seemed to be hurried. He had a serene temperament, a prodigious memory, and a genuine interest in the welfare of his patients, for each of whom, no matter how weary he may have been, he had a kind word. He abhorred the idea of destructive surgery and turned his attention more and more to plastic surgery, at which he soon became adept. Neill was well read and had an interest in many subjects, not least in history and the classics. To an extraordinary degree he had developed the faculty of reaching the core of a problem through a mass of detail. This enabled him to reach a reasoned decision in his work and helped to make him such an admirable secretary to the medical board and later to the medical advisory committee. He was a man of firm beliefs and opinions, but he saw the other man's point of view clearly enough never to irritate nor to give offence in a discussion. The main memory he leaves is one of quiet equanimity and unobtrusive hard work by which he achieved his aim—to become an "operating physician." In spite of much mental and physical suffering during the last few weeks of his life Neill remained calm, cheerful, and appreciative of the little that could be done to help him. To his widow and two baby daughters and to his parents his many friends extend their deep sympathy. —T. McL. G.

Dr. RAYMOND HENRY SHAW, who died in South Kensington on February 24 after a long illness, was born in Newcastle-upon-Tyne in November, 1866. His father, Benjamin Shaw, was a schoolmaster there, and his son was educated under him at Singleton House School. He studied medicine at Durham University, where he graduated M.B. with honours and B.S. in 1889; he had four scholarships there between 1886 and 1889, and he proceeded M.S., with first-class honours, in 1892, after holding an appointment as house-surgeon at the Royal Infirmary, Newcastle-upon-Tyne. About 1894 he joined the late Dr. Ryley in practice at Great Yarmouth, where he remained until he retired in 1932. He volunteered for the R.A.M.C. in the 1914-18 war, but was not accepted; and indeed his work at Yarmouth Hospital was probably of more advantage to his country than active service might have been. His house was hit during that war by a bomb, and his young daughter was wounded. Shaw had decided leanings towards surgery, though he was first and foremost a highly competent and successful general practitioner. He was surgeon to the Yarmouth General Hospital for about 24

years—much of that time senior surgeon. He was also surgeon to the Yarmouth police and medical officer to the Guardians' Infirmary and Children's Homes. He objected strongly to Lloyd George's National Health Insurance Act and led the opposition to it in his district. He was disappointed that it was finally brought into force and resigned his membership, never afterwards rejoining the Association. He married Miss Katharine Robson, of Darlington, in 1904. His wife and daughter survive him; his son, Raymond Thorndike Shaw, died of wounds while serving as a lieutenant-commander in the Royal Navy in 1942. After retiring Shaw made a good many voyages to the Far East as a ship surgeon, and to his great credit turned out again for this work during the last war. In 1942 his ship was hit by bombs off the coast of Scotland; he stayed in the ship until she was beached, incurring frost-bitten toes as a result—a fine record for a man of 75!

Medico-Legal

PRIVATE PATIENT'S FEES

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

In an action tried in the Willesden County Court¹ Judge Sir Henry Braund reduced the amount of a doctor's claim for fees from a private patient in respect of infra-red treatment and injections from £39 7s. 6d. to £25 15s. The claim was for 24 visits at 1½ guineas a time, with an initial visit at 3 guineas including a blood test.

The doctor said in evidence that he did not discuss the amount of his fee with the patient other than to say that his charge would be moderate as he knew she was not well off. He belonged to an old-fashioned generation of doctors who did not like to speak of money.

This case illustrates the principles of the English law of contract which affect the remuneration of doctors in private practice. The principles are of general application in the profession with the exception that a condition of admission to the Fellowship of the Royal College of Physicians is that a Fellow of the College may not sue for his fees.

In law the doctor in private practice can expressly agree with his patient any fee that is satisfactory to them both. If the patient will not pay, the doctor is entitled to sue him upon the express agreement for the amount agreed, and will recover that amount. Where the amount is expressly agreed it does not matter whether the court thinks it is too large or too small. It is for the parties to make their bargain, and the court will enforce the bargain they have made.

Alternatively, the patient may ask the doctor to treat him and the doctor may do so without either of them saying a word about the cost of the treatment. In that event the law implies a promise by the patient to pay a reasonable amount for the treatment, and, if the patient does not pay, the doctor is entitled to sue him upon this implied promise. The cause of action is called in the law of contract a *quantum meruit*. It is then for the court to say how much is "reasonable." The court in doing so applies objective considerations, and what the doctor or the patient may think is a reasonable fee is only an element in the evidence—to be taken into consideration together with any other evidence which may be adduced. The court will treat the evidence of expert witnesses called to say what in their opinion is a reasonable charge for the treatment given purely as a matter of opinion, giving it such weight as the expert who gives it can command. But it is for the court, after all the evidence has been given, to decide what is a reasonable amount. As Judge Sir Henry Braund observed in the Willesden case, what is reasonable in Harley Street may not be reasonable in Finchley Road.

If any doctor finds himself under the unpleasant necessity of having to sue for his fees, the advantages of having an express agreement to sue upon are therefore very great.

¹Hampstead and Highgate Express, February 23, 1951.

Medical Notes in Parliament

The National Drug

During the debate on the second reading of the Customs and Excise Bill on February 19 Dr. BARNET STROSS referred to the clause (229) dealing with tea, coffee, cocoa, etc. This contained paragraphs referring to the analysis of imported tea, which may have other substances added to it. He said that for 200 years it had been a national belief that to drink tea was good for one. He worked out that on an average consumption of 3 oz. (85 g.) of tea a week the total national intake of pure caffeine was about 50 million pounds a year (22.7 million kg.). There were about one and a half grains (100 mg.) of pure caffeine in the average strong cup of tea. Some people thought nothing of drinking 10 cups of tea a day, which would give them 15 gr. (1 g.) of caffeine. Yet the maximum medicinal dose of caffeine a day was 5 gr. (315 mg.). People who took an excessive amount of caffeine through their tea were the truest type of drug addicts, because caffeine was a true cerebral stimulant. The amount of alcohol found in beer and cider was not stimulating, and was ultimately depressing.

Mr. JOHN BOYD-CARPENTER, replying to the discussion, made no comment on this point.

Pneumoconiosis and Byssinosis

Mr. R. H. TURTON on February 20 moved that the House approve the Draft Pneumoconiosis and Byssinosis Benefit Scheme, 1952. He said that the Act of 1951 had set out provisions which this scheme embodied. It put uncompensated men and their dependants in the same position as if they were entitled to workmen's compensation for total disablement, or death from either disease. Whether a man was totally disabled or not, and whether death was a direct result of the disease, would have to be decided by a medical board.

Dr. EDITH SUMMERSKILL remarked that the scheme dealt only with the totally disabled, and hoped there would be further investigation in regard to the partially disabled. The scheme could be used for other diseases, and she asked Mr. Turton to consider such diseases as epithelioma.

Miss MARGARET HERBISON said that she and other members representing mining constituencies constantly had miners telling them that their own doctor diagnosed pneumoconiosis. Such cases were sent to Edinburgh Royal Infirmary, where a specialist, after an x-ray examination, decided that a man had pneumoconiosis, and he was thereafter sent to the medical board, which, in a number of cases, decided the man was not suffering from the disease. It was impossible to make a miner believe that he had a square deal when a specialist gave one decision and the medical board a different one. Mr. EDWARD DAVIES agreed that there was dissatisfaction because men felt that, while they had courtesy and an excellent service from the medical boards, there was often a conflict among medical men themselves on the diagnosis. The men must be assured that whoever had the responsibility of making a final decision in these matters was of the highest medical reputation.

Dr. BARNET STROSS said cases were known in which, because the disease was progressive, refusal in one year was followed by acceptance in the next, and asked whether that procedure would be continued. Mr. TURTON said that it would, and after further discussion he replied to the debate, reaffirming that on the interpretation of total disability and the question whether death arose from pneumoconiosis the decisions of medical boards would be final in future as at present. The House then agreed with the motion that the scheme be approved.

Cost of Patients' Food

Mr. T. F. PEART on February 25 asked the Minister of Health to give instructions to regional hospital boards that no economies should be made in hospital expenditure on

patients' food. Mr. H. F. C. CROOKSHANK answered that he could not do as suggested because this was within the discretion of hospital authorities, who might find it possible to secure some measure of economy without prejudicially affecting patients' diets.

Health Service Appliances

Mr. H. F. C. CROOKSHANK told Mr. A. BLENKINSOP on February 25 that the great variety of appliances supplied to patients through the hospitals in England and Wales during the 12 months ending December 21, 1951, could be broadly grouped under the following headings, for which the numbers and cost were:

Appliance	No. Supplied in 12 Months	Cost £
New surgical footwear	46,465	395,000
Appliances for lower limbs	28,280	156,000
Trusses	19,085	35,000
Abdominal appliances	107,282	375,000
Suprapubic and kindred appliances	15,570	55,000
Appliances for upper limbs	3,593	12,500
Spinal supports	58,656	410,000
Head and neck appliances	11,732	58,000
Elastic hosiery	35,520	80,000
Wigs	9,756	125,000
Prostheses (artificial breasts, ears, eyes, noses, etc.)	11,715	29,000
Artificial arms	1,937	51,500
" legs	11,383	330,000
" arm appliances	4,058	15,000
" eyes	7,682	12,000
Invalid chairs and tricycles	10,108	685,073

Safety on the Roads

Brigadier FRANK MEDLICOTT on February 28 asked the Home Secretary to take steps to make a blood test for alcohol compulsory in the case of the driver of a vehicle involved in an accident which caused death or injury to any person. Sir DAVID MAXWELL FYFE replied that the proposal involved a serious encroachment on personal liberty. On his present information he would not feel justified in proposing such a fundamental alteration in the law.

Mr. J. S. MACLAY stated that, in the absence of evidence that defective eyesight of drivers was an important factor in road accidents, he did not think that further steps were necessary to ensure that the eyesight of drivers was sufficiently good to prevent accidents. He added that a requirement that some individuals should wear glasses while driving would be unenforceable.

Artificial Limbs.—No charge will be made for artificial limbs, for most surgical aids needed by the seriously disabled, nor for any appliances supplied to patients who are resident in hospital rehabilitation centres.

"Roter" Tablets.—Mr. H. F. C. Crookshank has stated that these proprietary tablets for treatment of peptic ulcer could not be regarded as essential. He was therefore unable on medical grounds to recommend that import restrictions should be waived.

Vital Statistics

Smallpox in Lancashire

The total number of cases of variola minor ascertained up to the morning of Tuesday, March 4, was, 70 (64 in Rochdale, 5 in Milnrow, and 1 in Heywood). All these cases are associated with the original focus in Rochdale. Thirty-seven cases are in hospital. The remainder are no longer infectious. Until March 3 the cases had occurred in the direct line of contact. On March 3, 4 cases were found which cannot at present be associated with previous cases. There is no report of smallpox in any other part of the country.

Industrial Accidents and Diseases

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in January was 131, compared with 99 in the previous month and 140 (revised figure) for January, 1951. Of these deaths 41 were underground in coal mines and 18 were in building operations.

The following cases of industrial disease were notified during the month: lead poisoning 4, aniline poisoning 4, toxic anaemia 1, anthrax 2, epitheliomatous ulceration 11, chrome ulceration 20 (chromium plating 10); total 42. There were no deaths (*Ministry of Labour Gazette*, February, 1952).

During 1951, 485 persons were killed in coal mines and 1,942 seriously injured, as compared with 493 and 2,020 (revised figure) respectively in 1950.

Infectious Diseases

A rise in the number of notifications was recorded in England and Wales for the week ending February 16 for measles 555, scarlet fever 65, and dysentery 44, while the only fall of any size was 136 for whooping-cough.

A small rise in the incidence of measles was recorded in many areas. The largest rises were Cheshire 166 and Middlesex 98, while the only large exception to a rising trend was a fall of 172 in Lancashire. With the exception of a small rise in London and the adjacent counties, the incidence of scarlet fever remained practically constant. The only large variation in the local trends of whooping-cough was a decline of 87 in Yorkshire West Riding. The notifications of diphtheria were 14 more than in the preceding week. The rise in diphtheria was chiefly contributed by Lancashire with an increase of 8; 10 cases were notified in Darwen M.B., where 5 cases were reported in the preceding week.

The number of notifications of acute poliomyelitis were 2 more for paralytic and 1 more for non-paralytic cases than in the previous week. The only administrative area with more than 1 case was Sussex, Southwick U.D., with 2 cases.

An important factor in the increased incidence of dysentery was a rise of 86 in the number of notifications in Lancashire. A further 62 cases were notified in the outbreak in Norwich C.B., bringing the total notifications for this centre up to 984. The largest returns during the week were Lancashire 157 (Oldham C.B. 46, Manchester C.B. 36, Chadderton U.D. 11, Bolton C.B. 10); London 83 (Hackney 23, Wandsworth 11); Norfolk 72 (Norwich C.B. 62); Middlesex 51 (Willesden M.B. 18); Yorkshire West Riding 34 (Leeds C.B. 13); and Surrey 33.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported during the nine years 1943-51 are shown thus -----, the figures for 1952 thus ————. Except for the curves showing notifications in 1952, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

**Week Ending February 23**

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,613, whooping-cough 2,648, diphtheria 37, measles 5,734, acute pneumonia 1,143, acute poliomyelitis 14, dysentery 591, paratyphoid fever 6, and typhoid fever 3.

Census Changes.—Population figures obtained at the 1951 census show that there are now 160 great towns (population over 50,000) in England and Wales instead of 126, and 17 principal towns (population over 30,000) in Scotland instead of 16. Therefore the 1952 figures for deaths, births, and stillbirths in these countries, published weekly in our Table, cannot be accurately compared with those for 1951, which are printed in italics. The 160 great towns in England and Wales have a population about 10% higher than the 126.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending February 16 (No. 7) and corresponding week 1951.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (London included), London administrative county, the 17 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Senate on February 23 approved an Address to Her Majesty the Queen expressing condolence on the death of His Majesty King George VI and the respectful homage of the University to Her Majesty on her succession to the Throne. An Address of condolence to Her Majesty Queen Elizabeth the Queen Mother was also approved.

The following medical degrees were conferred on February 23:

M.CHIR.—*G. M. Lunn.

M.B., B.CHIR.—*R. F. Pearson, *Katharine C. Paterson, I. H. Kerr, C. McC. Campbell.

The following candidates have been approved at the examination indicated:

M.CHIR.—T. Fenwick, T. W. Rowntree, R. N. Ticehurst, W. Waugh.

*By proxy.

UNIVERSITY OF LONDON

The following have been recognized as teachers of the University in the subjects indicated in parentheses: *St. Bartholomew's Hospital Medical College*, Dr. H. F. Brewer and Dr. H. Lehman (Pathology); Dr. C. S. Nicol (Venereal Diseases); Mr. A. S. Philips (Ophthalmology); Dr. B. F. Russell (Dermatology). *Postgraduate Medical School of London*, Dr. E. G. L. Bywaters and Dr. J. F. Goodwin (Medicine); Mr. M. R. Ewing, Mr. R. H. Franklin, Mr. G. C. Knight, and Mr. R. Shackman (Surgery). *National Institute for Medical Research*, Dr. O. G. Endholm (Physiology). *Charing Cross Hospital Medical School*, Dr. J. A. Gorsky (Forensic Medicine); Dr. S. Shaw (Pathology). *University College Hospital Medical School*, Dr. W. Grossman (Dental Surgery); Miss Doreen Nightingale (Surgery). *St. George's Hospital Medical School*, Mr. J. J. Richmond (Radiology). *St. Mary's Hospital Medical School*, Mr. I. G. Robin (Oto-rhinolaryngology); Dr. K. W. Cross (Physiology). *University College*, Dr. R. D. Harkness (Physiology); Dr. S. E. Dicker (Pharmacology). *School of Pharmacy*, Dr. Eleanor J. Zaimis (Pharmacology). *St. Thomas's Hospital Medical School*, Dr. J. R. Napier (Anatomy).

Dr. B. A. D. Stocker has been granted probationary recognition as a Teacher of Pathology at the London School of Hygiene and Tropical Medicine for two years from December, 1951.

The following, who are already recognized teachers at undergraduate medical schools, have been recognized also as teachers at the postgraduate institutes and in the subjects indicated: *Institute of Obstetrics and Gynaecology*, Mr. I. M. Jackson (Obstetrics and Gynaecology). *Postgraduate Medical School of London*, Mr. C. H. Gray (Surgery).

The William Julius Mickle Fellowship for 1951-2 has been awarded to Rosalind Venetia Pitt Rivers, M.Sc., Ph.D., in respect of the investigations into biochemical and physiological problems connected with thyroxine and kindred substances which she has carried out during the past five years.

In Convocation on January 19 it was announced that Drs. C. A. H. Franklyn and W. J. O'Donovan had been re-elected as representatives of the Faculty of Medicine on the Standing Committee of Convocation for a period of three years.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council held on February 18 it was decided to send a Loyal Address to Her Majesty Queen Elizabeth II.

The Council has appointed S. R. Elsdon, Ph.D., Senior Lecturer in Microbiology, to be in charge of a separate Department of Microbiology, the arrangements to take effect from October 1.

The Council received the resignations of Dr. L. G. Cook, Honorary Lecturer in Bacteriology, on his return to New Zealand, and Dr. B. A. E. Johns, Lecturer in Anatomy, who is returning to clinical work, and thanked them for their services to the University.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

At a quarterly meeting of the college, held on February 5, with the President, Dr. W. A. Alexander, in the chair, the following were elected Fellows of the College: C. M. Fleming, W. Henderson, H. E. Seiler, I. H. L. Gillies, W. H. Galloway.

The following were elected Members of the College: W. Boyd, Irene P. Rowlands, S. Stein, R. Orton, J. N. Armour, G. W. Reid, V. D. Bayliss, S. Prakash, H. McD. Forde, N. Gordon, R. Prasad, B. M. Kher, L. Albert, J. Gant, M. P. Mehrotra, Jean C. Taylor, H. Black, A. C. Douglas, P. C. MacGillivray, M. A. Botawala, S. D. Store, R. S. M. D. Inch.

Medical News

Anglo-French Medical Exchange Bursaries.—The French Embassy in London has recently negotiated an agreement between the Institut National d'Hygiène, Paris, and the Ciba Foundation, London, for an exchange of short-term grants to enable young British and French doctors to visit each others' countries and study special techniques. The grants, which will have a minimum value of £50 a month tax-free, will normally be awarded for a minimum of two and a maximum of six months. The bursaries are intended primarily for doctors wishing to obtain clinical experience, but they can also be awarded for medical research. Candidates must have had at least one year's experience after qualification and must indicate in their application the place in which they wish to carry out their study. Candidates for the French bursaries must be British subjects and citizens of the United Kingdom. They will be chosen by a selection board. Applications for the 1952 bursaries should be made before March 31 to Dr. G. Wolstenholme, Ciba Foundation, 41, Portland Place, London, W.1, from whom application forms can be obtained.

Manchester Medical Society.—On January 28 the inaugural meeting of the new section of general practice was held with Dr. R. R. Kerr in the chair. This section has been formed at the request of a large number of Manchester general practitioners with the object of holding meetings at times convenient to them and to enable them to have lectures and discussions on problems closely connected with general practice. Any general practitioner in Manchester and district who is interested in becoming a member is invited to communicate with the honorary secretary of the Manchester Medical Society at Manchester University.

Liverpool Medical Institution.—At a meeting on February 14 Dr. R. B. MacKenna read a paper entitled "Some Problems in Dermatology," and discussed four problems in dermatology. Infantile eczema, particularly the atopic type of that malady, was a matter in which an ecological survey would be likely to be helpful. Psoriasis was probably a dermatome—that is, the eruption on the skin was but the cutaneous part of a syndrome in which the endocrine system was principally involved. Thirdly, cross-sensitization phenomena were considered, and finally he stated that work done by Dr. Ida Macalpine in his department at St. Bartholomew's Hospital indicated that certain cases of recurrent dermatitis of the eyelids, which hitherto had been widely regarded as being invariably due to allergic sensitivities, were sometimes manifestations of nervous stress and were not really manifestations of allergy.

In the discussion which followed Dr. J. M. H. Smellie said he would like to mention a case of arthritic psoriasis, which Dr. MacKenna had seen in consultation with his (Dr. Smellie's) old colleague, Dr. Gerald Wallace. Dr. Smellie was asked to help in mobilizing her shoulders, elbows, hips, and knees to make her fit on a frame, prior to her admission to hospital. There the first injection of "mercaloid" produced albuminuria and vomiting, and the second made her so much worse that she was taken home. Her father, resigned to her being a permanent invalid, had doors fitted to the back of his car to admit her invalid chair. For some months he continually declared that he would give his right arm if only his daughter could be cured. Later, while on holiday, his car, with wife and daughter on board, was involved in a crash. The father had his right arm severed at the shoulder. Before the father's wound was healed the daughter's psoriasis and arthritis had disappeared. Dr. Smellie asked whether Dr. MacKenna attributed this to psychological agencies or to liberation of cortisone following adrenal shock.

Caernarvonshire and Anglesey Paediatric Club.—The club was formed in December, 1950, to encourage discussion and further knowledge on infant care and management among both lay and medical men. Meetings are held usually at the County Hospital, Bangor, on the third Tuesday in every month at 4.30 p.m., except in June, July, and August.

Membership is open to doctors, health visitors, district nurses, and all persons interested in paediatrics, and further information may be obtained from the secretary, Dr. G. W. Roberts, St. Fillans, Segontium Road South, Caernarvon.

British Rehabilitation Methods Applied in Austria.—Dr. Walter Ehalt, who is director and chief surgeon of the Graz Accident Hospital, was one of two Austrian medical men to attend the 1948 British Council course on the rehabilitation and resettlement of the disabled. On their return they arranged for the establishment of the first rehabilitation and vocational training centre in Austria on the British model. It was set up by the Austrian Insurance Board, which administers the industrial disability compensation scheme. Dr. Ehalt is now (February 25–March 11) making a further study of British treatment of the disabled at the Royal National Orthopaedic Hospital, the London Hospital, the Wingfield-Morris Hospital, Oxford, the Ministry of Pensions Hospital, Stoke Mandeville, the Birmingham Accident Hospital and Rehabilitation Centre (March 7 and 8), and at Manchester Royal Infirmary (March 10).

Hospitals Menace Homes.—The 26 teaching hospitals in London will eventually require another 195 acres of land for their planned extension, which will mean pulling down the houses of 13,800 people to yield the necessary space. The Middlesex Hospital, in Mortimer Street, W.1, is typical. Central London is very densely populated, and planned expansion of the hospital into adjoining property will mean moving 710 people out of 140 houses, 35 shops, two public houses, and seven "other premises." These are some of the startling facts shown by the exhibition of plans, drawings, photographs, and models now at County Hall to illustrate the London County Council's development proposals under the Town and Country Planning Act, 1947. Objections to the plan, which is subject to a quinquennial review, have to be lodged with the L.C.C. by March 16. It is intended to keep the Harley Street district as a medical area.

Oxford and Cambridge Boat Race.—Messrs. Vitamins Limited announce that they have available a limited number of tickets for doctors who may wish to view the Boat Race on March 29 from their premises. Early application should be made to Dept. B.R.2, Vitamins Limited, Upper Mall, London, W.6.

Publications Received.—*National Register of Medical Auxiliary Services: Speech Therapists:* Board of Registration of Medical Auxiliaries, B.M.A. House, Tavistock Square, London, W.C.1, 1951 (free on application). *Catalogue of Oriental Manuscripts in the Library of the Royal College of Physicians:* reprinted from the *Journal of the Royal Asiatic Society* (apply to Harveian Librarian).

Emergency Bed Service: Applications and Admissions.—During the seven days ending March 3 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,138, of whom 87.52% were admitted.

Will.—Dr. Frank Hubert Robbins left £30,517. He left £200 to the Royal Medical Benevolent Fund in memory of his son Tony.

COMING EVENTS

Postgraduate Course in Venereology.—The Institute of Urology announces that a postgraduate course on venereology will be held at St. Paul's Hospital, Endell Street, W.C.2, at 11 a.m., from March 3 to 30. Full details from the secretary of the Institute, Henrietta Street, W.C.2.

Public Health Course.—The Royal Institute of Public Health and Hygiene announces that the next biannual course of instruction for the Certificate in Public Health, which leads to courses for both the Diploma in Public Health and the Diploma in Industrial Health, will commence on Friday, March 21. All courses may be taken either whole-time or part-time. Prospectuses, enrolment

forms, and full details may be obtained from the secretary of the Royal Institute of Public Health and Hygiene, 28, Portland Place, London, W.1.

Medical Teaching.—A conference-course on the technique of medical teaching will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, on March 28 and 29. The programme includes "Teaching Teachers," by Sir Geoffrey Jefferson; "The Influence of Examinations on Teaching," by Professor Harold Rodgers; "The Clinical-pathological Conference," by Professor J. H. Dible; "The Training of the Research Worker," by Professor E. J. Wayne; "Visual Methods," by Dr. R. G. W. Ollerenshaw; "Practical Clinical Instruction," by Professor C. Bruce Perry; and "The Education of the General Practitioner," by Dr. G. O. Barber. Admission by ticket only on application from the Postgraduate Medical School, Du Cane Road, W.12.

18th International Neurological Reunion.—This will be held in Paris on July 8 and 9, and will deal with the study of pathological movement. Those interested are requested to register before May 1, and all details may be obtained from M. Jean Sigwald, 68, Boulevard de Courcelles, Paris, 17^e.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday

INSTITUTE OF NEUROLOGY, National Hospital, Queen Square, London, W.C.—March 10, 5 p.m., "*The Physiological Responses of Chromatolysed Neurones*," Guest Lecture by Professor J. C. Eccles, F.R.S.

INSTITUTE OF PSYCHIATRY, Maudsley Hospital, Denmark Hill, London, S.E.—March 10, 5.30 p.m., lecture-demonstration for postgraduates by Dr. E. Stengel.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—March 10, 8.30 p.m., "*Therapeutic Trauma of the Brain*," discussion to be introduced by Dr. G. W. B. James and Dr. P. M. Tow.

Tuesday

CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 41, Queensgate Terrace, London, S.W.—March 11, 8.30 p.m., 6th ordinary meeting of 55th session. "*The School Doctor looks Forwards and Backwards*," discussion to be opened by Dr. R. E. Smith.

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—March 11, 5.30 p.m., "*Contact Allergy*," by Dr. S. C. Gold.

MANCHESTER MEDICAL SOCIETY.—At Physiology Theatre, Medical School, Manchester University, March 11, 4.30 p.m., joint meeting of Section of Surgery and Medicine. "*The Treatment of Haematemesis*," by Dr. F. Avery Jones.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, London, S.W.—March 11, 5 p.m., "*The Dynamics of Heart Failure*," Oliver-Sharpey Lecture by Dr. J. McMichael. (See also March 13.)

WEST END HOSPITAL FOR NERVOUS DISEASES, 40, Marylebone Lane, London, W.—March 11, 5.30 p.m., neurological demonstration by Dr. T. Rowland Hill.

Wednesday

CAMBRIDGE UNIVERSITY.—At Department of Physical Chemistry, Free School Lane, Cambridge, March 12, 12 noon, "*Some Aspects of the Physical Chemistry of Amino-acids, Peptides, and Proteins*," by Professor John T. Edsall (Harvard University).

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—March 12, 5.30 p.m., "*The Origin of Epithelial Neoplasms in the Skin*," by Dr. I. W. Whimster.

INSTITUTE OF NEUROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C.—March 12, 4.30 for 5 p.m., "*Differential Diagnosis of Renal Pain*," by Mr. J. E. Semple.

LONDON COUNTY MEDICAL SOCIETY.—At Paddington Hospital, Harrow Road, W., March 12, 3 p.m., clinical meeting.

MANCHESTER MEDICAL SOCIETY: SECTION OF PATHOLOGY.—At Medical School, Manchester University, March 12, 4.30 p.m., "*Porphyria in Health and Disease*," by Dr. J. B. Kench.

Thursday

ALFRED ADLER MEDICAL SOCIETY.—At 11, Chandos Street, London, W.—March 13, 8 p.m., "*The Relationship of Body and Mind*," by Dr. E. K. Ledermann. Discussion to be opened by Dr. E. B. Strauss.

●INSTITUTE OF CHILD HEALTH, Hospital for Sick Children, Great Ormond Street, London, W.C.—March 13, 5 p.m., "*The Ear, Nose, and Throat*," by Mr. H. S. Sharp.

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—March 13, 5.30 p.m., "*Histopathology of Foreign Body and Specific Granulomas*," by Dr. H. Haber.

LIVERPOOL MEDICAL INSTITUTION, 114, Mount Pleasant, Liverpool.—March 13, 8 p.m., pathological meeting.

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Dorchester Hotel, Park Lane, London, W., March 13, 6.30 p.m. to 1 a.m., annual dinner dance.

MANCHESTER MEDICAL SOCIETY: SECTION OF ANAESTHETICS.—At Staff House, Manchester University, March 13, 8.15 p.m., "*The Control of Bleeding During Surgical Operations*," by Dr. W. B. Bacon and Dr. C. E. Sykes.

MEDICAL SOCIETY FOR THE CARE OF THE ELDERLY.—At Old Library, B.M.A. House, Tavistock Square, London, W.C., March 13, 11.30 a.m., Conference on Co-ordinated Medical Care of the Elderly. Introductory Address by Lord Amulree. "Co-ordinated Medical Care of the Elderly," to be opened by Dr. J. A. Scott, Dr. E. B. Brooke, and Dr. Barbara Morton. A general discussion will follow. 4.30 p.m., annual general meeting.

ROYAL ARMY MEDICAL COLLEGE.—At Lecture Theatre, John Islip Street, London, S.W.—March 13, 5 p.m., "*Common Difficulties in the Diagnosis of Heart Disease*," by Dr. D. Evan Bedford.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, London, S.W.—March 13, 5 p.m., "*The Dynamics of Heart Failure*," Oliver-Sharpey Lecture by Dr. J. McMichael. (See also March 11.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—March 13, 5 p.m., "*Ureteric Calculus*," Hunterian Lecture by Professor V. W. Dix.

ST. ANDREWS UNIVERSITY.—At Lecture Theatre, Materia Medica Department, Medical School, Small's Wynd, Dundee, March 13, 5 p.m., "*Transmission of Effects from Nerve Endings—A Survey of the Significance of Present Knowledge*," by Sir Henry Dale, O.M., F.R.S.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—March 13, 4.30 p.m., lecture-demonstration in psychiatry by Dr. D. Curran.

UNIVERSITY COLLEGE, Physiology Theatre, Gower Street, London, W.C.—March 13, 4.45 p.m., "*Mitochondria and Biological Oxidations and Phosphorylations*," by Dr. A. L. Lehninger (Chicago).

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, University Street, Gower Street, London, W.C.—March 13, 5 p.m., "*The Structural and Functional Plasticity of Influenza Viruses*," Sydney Ringer Memorial Lecture by Professor Wilson Smith, F.R.S.

Friday

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—March 14, 5.30 p.m., "*Contact Eczema*," clinical demonstration by Dr. S. C. Gold.

●INSTITUTE OF DISEASES OF THE CHEST AND INSTITUTE OF CARDIOLOGY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., March 14, 5.30 p.m., "*Surgical Treatment of Mitral Stenosis*," by Mr. R. C. Brock.

OXFORD UNIVERSITY.—At Magdalen College, Oxford, March 14, 5 p.m., "*The Neurophysiological Basis of Mind*," Waynflete Lecture by Professor J. C. Eccles, F.R.S.

APPOINTMENTS

BUCHANAN, JAMES ANDREW, M.B., Ch.B., D.P.H., County Medical Officer of Health, Banffshire.

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—Consultant Pathologist to Hospitals in Peterborough and King's Lynn Area, A. M. Pugh, M.B., Ch.B., D.T.M.&H. Consultant Radiologist in East Suffolk and Ipswich Area, K. E. Barlow, M.R.C.S., L.R.C.P., D.M.R., F.F.R. Consultant Orthopaedic Surgeon in East Suffolk and Ipswich Area, T. Denness, M.Ch.Orth., F.R.C.S. Registrar in Psychiatry, Fulbourn Mental Hospital, Fulbourn, Cambs, Elisabeth Shoenberg, M.R.C.S., L.R.C.P.

FLEMING, G. M., M.D., D.P.H., Medical Officer of Health and School Medical Officer, County Borough of West Bromwich.

GROSS, DESIREE, M.B., M.D., D.P.H., Deputy Medical Officer of Health, Borough of Ilford, and Assistant County Medical Officer, Essex County Council.

LIVERPOOL REGIONAL HOSPITAL BOARD.—Whole-time Assistant Pathologist to Hospitals in Ormskirk Area, R. G. Tasker, M.B., B.Chir. Whole-time Assistant Pathologist to Walton Hospital, M. J. Wodzinski, M.D. Whole-time Assistant Psychiatrist to Rainhill Hospital, G. C. Heller, M.D. Whole-time Assistant Psychiatrist to Winwick Hospital, P. M. O'Flanagan, L.R.C.P.&S.I., D.P.M. Whole-time Consultant Psychiatrist to Rainhill Hospital, S. Falk, M.D., D.P.M. Consultant Surgeon to Regional Thoracic Unit, J. K. B. Waddington, F.R.C.S.Ed.

MCCOLL, MICHAEL, M.B., Ch.B., D.P.M., Deputy Medical Superintendent, and Consultant Psychiatrist, Barnsley Hall Hospital, Bromsgrove, Birmingham Regional Hospital Board.

MANCHESTER REGIONAL HOSPITAL BOARD.—Consultant Psychiatrist, Preston and Chorley Hospital Centre, and Whittingham Hospital, C. S. Parker, M.D., D.P.M. Consultant General Physician, Macclesfield Hospital Centre, F. W. Smith, M.B., Ch.B., M.R.C.P. Consultant Obstetrician/Gynaecologist, Crewe Hospital Centre, H. D. Freeth, M.D., M.R.C.O.G. Consultant General Physician, Crumpsall Hospital, Manchester, M. H. Oelbaum, M.D., M.R.C.P. Consultant Obstetrician/Gynaecologist, Park Hospital, Davyhulme, D. C. A. Bevis, M.B., Ch.B., M.R.C.O.G. Assistant Anaesthetist, Rochdale Hospitals (S.H.M.O.), S. Mehlmann, M.D. Assistant Psychiatrist, and Deputy Medical Superintendent, Calderstones Hospital (S.H.M.O.), E. M. Hutton, M.B., B.Ch. Tuberculosis Physician, Wigan and Leigh Hospital Areas, C. D. Rushworth, M.R.C.S., L.R.C.P.

SHIEL, JOHN B., M.B., Ch.B., D.P.H., County Medical Officer, Stewartry of Kirkcudbright.

SOUTH-WEST METROPOLITAN REGIONAL HOSPITAL BOARD.—*Whole-time Deputy Physician-Superintendent and Consultant Psychiatrist, St. Lawrence's Hospital, Caterham, J. J. Ryan, M.B., B.Ch., D.P.H., D.P.M. Part-time Assistant Ophthalmologists (S.H.M.O.), Portsmouth Group of Hospitals, T. G. S. Murray, M.R.C.S., L.R.C.P., D.O.M.S., A. E. Barrett, M.R.C.S., L.R.C.P., D.O.M.S. Whole-time Assistant Radiotherapist (S.H.M.O.), Lambeth Hospital, R. Parfitt, M.R.C.S., L.R.C.P., D.M.R.T. Part-time Consultant Orthopaedic Surgeon, St. Heller Group of Hospitals, H. H. Kennedy, F.R.C.S.Ed. Part-time Consultant Surgeon, Portsmouth Group of Hospitals, W. W. Wiggins-Davies, M.Chlr., F.R.C.S. Part-time Consultant Dermatologist, Portsmouth and Isle of Wight Groups of Hospitals, A. A. C. Ross, M.B., Ch.B., M.R.C.P.Ed. Registrar to Medical Department, Royal Victoria and Christchurch Hospitals, Bournemouth, C. C. Downie, M.B., Ch.B. Registrar to Surgical Department, St. Luke's Hospital, Guildford, J. F. Shaw, M.B., B.S. Senior Registrar to Orthopaedic Surgery Department, Southampton and Isle of Wight Groups of Hospitals, E. H. J. Smyth, M.B., B.S., F.A.C.S. Registrar to Surgical Department, St. Stephen's Hospital, J. L. Swann, M.B., B.S., F.R.C.S. Registrar to Obstetric and Gynaecological Department, Redhill County Hospital, M. G. Pearson, M.B., Ch.B., M.R.C.O.G. Registrar to Pathological Department, Royal Victoria Hospital, Bournemouth, Eileen A. Hunter, M.B., Ch.B. Registrar to Orthopaedic Surgery Department, Lord Mayor Treloar Orthopaedic Hospital, Alton, I. G. MacKenzie, M.D., F.R.C.S.Ed. Senior Registrar to Thoracic Surgery Department, Southampton Infectious Diseases Hospital, G. Katz, M.B., B.Ch., F.R.C.S. Registrar to Anaesthetic Department, Queen Mary's Hospital, Carshalton, M. Flynn, M.B., B.Ch.*

TRYTHALL, D. A. H., M.D., M.R.C.P., D.C.H., Assistant Medical Registrar, Hospital for Sick Children, Great Ormond Street, London, W.C.

WILSON-SHARP, CECIL DEREK, M.B., B.S., D.M.R.D., Senior Registrar, Department of Radiodiagnosis, The London Hospital, E.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Alexander.—On February 22, 1952, to Nancy (formerly Walmsley), wife of Francis G. Alexander, M.B., Ch.B., of Small Heath, Birmingham, a sister for David and Alison.

Orford Smith.—On February 15, 1952, at the Queen Elizabeth Hospital, to Mary, wife of Dr. E. S. Orford Smith, of 59, Hagley Road West, Harborne, Birmingham, a sister for John David and Margaret.

DEATHS

Ainsworth.—On February 13, 1952, at the Royal West Sussex Hospital, Hugh Ainsworth, M.B., F.R.C.S., Colonel, I.M.S., retired.

Armstrong.—On February 19, 1952, at Braintree, Essex, John Thomas Armstrong, L.R.C.P.&S.Ed., L.R.F.P.S., of the Constitutional Club, London, W.C.

Brown.—On February 16, 1952, William Brown, L.R.C.P.&S.Ed., L.R.F.P.S., of Bursage Road, London, S.E.

Campbell.—On February 16, 1952, John Alexander Langford Campbell, O.B.E., M.D., Surgeon Captain, R.N., retired, of 24, Norfolk Road, London, N.W.

Cuthbert.—On February 20, 1952, at Edinburgh, James Mackie Cuthbert, M.B., Ch.B., Major, R.A.M.C., retired.

Davies.—On February 20, 1952, at Morannedd, Towyn, Merioneth, John Alban Davies, L.M.S.S.A.

Devlin.—On February 17, 1952, at Old Chapel House, Richmond Hill, Leeds, James Francis Patrick Devlin, M.B., B.Ch., aged 59.

Douglas.—On February 2, 1952, at Hamilton, New Zealand, Mary Douglas, M.B., Ch.B., D.R.C.O.G.

Dowler.—On February 19, 1952, at The Limes Nursing Home, Burgess Hill, Sussex, Herbert Matthew Dowler, M.R.C.S., L.R.C.P., of Mussoorie, United Provinces, India, aged 83.

Eames.—On February 15, 1952, at Shrewsbury, John Ward Eames, M.B., Ch.B., Colonel, A.M.S.

Graves.—On February 11, 1952, at Worthing, Sussex, Charles Frederick Graves, L.R.C.P.&S.Ed., L.R.F.P.S., formerly of Paddington, London, W.

Hall.—On February 15, 1952, at 9, Dellfield Close, Watford, Herts, Charles Herbert Hall, M.D., aged 84.

Hartley.—On February 18, 1952, at 29, Lower Oxford Street, Castleford, Yorks, Walter Dixon Hartley, M.B., B.S., aged 74.

Hicks.—On February 12, 1952, Charles Edward Hicks, M.R.C.S., L.R.C.P., of St. Ives, Huntingdon, aged 77.

Hobbs.—On February 21, 1952, at Trundle Nursing Home, Caterham, John Hobbs, L.R.C.P.&S.I. & L.M., Major R.A.M.C., retired, of 22, Timber Hill, Caterham, Surrey, aged 89.

Leckie.—On February 18, 1952, at Perth, Joseph Primrose Leckie, M.B., F.R.C.P.Ed., of the Hydropathic, Crieff, Perthshire.

McCalden.—On February 13, 1952, Joseph Crawford Alfred McCalden, M.B., B.Ch., of 60, Kingston Crescent, Portsmouth.

Matheson.—On February 3, 1952, Ian Henry Matheson, M.B., Ch.B., of Coombe House, Halberton, Tiverton, Devon, aged 44.

Morcom.—On February 12, 1952, at 41, South Eaton Place, London, S.W., Alfred Farr Morcom, M.B., B.Ch.

Nash.—On February 8, 1952, at Strawberry Cottage, Sandhurst, Camberley, Berks, Charles Henry Nash, L.R.C.P.&S.Ed., L.R.F.P.S.

Orr.—On February 15, 1952, at Edinburgh, William Basil Orr, M.D., of 2, South Learmonth Avenue, Edinburgh.

Patton.—On February 20, 1952, William Patton, M.B., Ch.B., of Dunarnon, Amersham, Bucks.

Pearson.—On February 18, 1952, at Greystead, Blackwell Scar, Darlington, Henry Carden Pearson, M.B., F.R.C.S.Ed., aged 77.

Scott.—On February 4, 1952, at Ruan High Lanes, Truro, Cornwall, Frank Sholl Scott, M.B., B.S., aged 68.

Spence.—On February 7, 1952, at Bognor Regis, Sussex, Harold Douglas Livingstone Spence, M.D., M.Ch.

Thomas.—On February 6, 1952, at the home of his nephew, 15, Prospect Row, Brompton, Chatham, Kent, John Henry Thomas, M.R.C.S., Fleet Surgeon, R.N., retired, aged 94.

Tripp.—On February 2, 1952, Charles Llewellyn Howard Tripp, M.R.C.S., L.R.C.P., late of the Falcon Hotel, Bude, Cornwall, aged 94.

Waterfield.—On February 6, 1952, at Beach Haven, Hooc, Plymouth, Devon, William Henry Waterfield, L.R.C.P.&S.I. & L.M., late of Stonehouse, Plymouth, aged 89.

Wells.—On February 17, 1952, at Tylers Cross, Roydon, Essex, John Edmund Bishop Wells, M.R.C.S., L.R.C.P., Major, R.A.M.C., T.F., retired.

Willis.—On February 10, 1952, at 96, Evington Drive, Leicester, David Victor Stewart Willis, M.B., B.Ch., late of Walsall, Staffs, aged 65.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Night Nurses' Paralysis

Q.—What is the explanation of night nurses' paralysis?

A.—Night nurses' paralysis is a frightening but banal condition. It usually occurs during the early hours of the morning when the nurse is sitting at her table in the darkened ward; suddenly someone enters the ward or a patient shouts for assistance and the nurse finds herself quite unable to move or even to speak for some seconds, though the period of "paralysis" may seem to be much longer than this. Suddenly power returns and she is able to carry on with her duties. This condition is the same as the "sleep paralysis," which is not uncommon—that inability to move, often accompanied by anxiety, which may occur as a person is just going off to sleep or more commonly on first awakening. The explanation seems to be that the motor and postural centres "fall asleep" before the mind, or during the process of waking the mind "wakens" before the motor and postural centres (*British Medical Journal*, 1939, 2, 51). The problem is of course more involved than this: there is obviously similarity to cataplexy with the transient loss of power and tone in response to a sudden emotional stimulus, and it may also be significant that attacks of familial periodic paralysis which are recognized to be associated with a fall in the blood potassium are nearly always at their maximum intensity on first waking in the morning. More knowledge of the actual physiology of sleep is necessary before a complete answer can be given to this question.

Psychological Effects of Female Castration

Q.—How real is the risk that a bilateral oophorectomy will have serious psychological consequences in a woman of 41?

A.—Bilateral oophorectomy carried out in a woman aged 41 years will almost certainly be followed by some menopausal symptoms. These will mainly take the form of hot flushes, and their severity and duration are variable. Symptoms are severe in about half the cases. In a stable woman there is no need to fear serious nervous reaction, possibly some temporary emotional upset at most. In an unstable woman, however, the risk is much higher and depends on the degree and type of the present instability. If she has been subject to mental disorder in the past the operation might well cause a relapse. Each case needs to be judged on its merits, and the outlook of individual patients on the menopause is important.

Pneumonectomy for Bronchiectasis

Q.—What are the indications for and against lung resection in the treatment of bronchiectasis?

A.—Two factors play important parts in the selection of cases for lung resection: (1) The distribution and extent of the bronchiectasis: the more localized and limited the disease the better for surgery. (2) The age of the patient and the ability to survive on what lung tissue is left behind. The ideal case is that of a child with cough and sputum and with the disease limited to a lobe. Here the results of surgery are excellent. Elderly, emphysematous patients with diffuse bilateral disease are not suitable.

In assessing a patient complete bilateral bronchograms are necessary, and gross upper respiratory infection must be eliminated or reduced. Also pulmonary tuberculosis should be excluded. Patients with toxæmia and excessive sputum are in more urgent need of surgery than those whose symptoms are less obvious. Bronchiectatic changes in both lungs are less favourable than when the same amount of disease is concentrated in one lung, but limited bilateral operations in patients under middle age are quite practicable. As much as one lung or three lobes (the lingula being counted as a lobe) may be removed, particularly if the disease is gross and the lung has been rendered functionless. If the disease is diffuse and involves only parts of lobes, several segmental resections can be performed, but diffuse disease is more likely to be progressive than lobar bronchiectasis, which may have had its origin in bronchial obstruction by enlarged hilar glands. Too much attention need not be paid to the type of bronchiectasis—e.g., saccular, cystic, or fusiform; it is the symptoms and extent of the change that count. An age limit of about 40 years is usual, though in the absence of emphysema and with supple chest movements this may be extended. At the other extreme, if possible, operation should be postponed until a child can co-operate in the postural and physical treatment that are essential both before and after operation.

Is Bread Good for Diabetics?

Q.—Is bread a good food for diabetics? If not, what alternatives are suggested?

A.—Bread is an excellent food for a diabetic patient to eat. One ounce (28.4 g.) of our present national wheatmeal (85% extraction) contains 15.7 g. of carbohydrate, expressed as a glucose, and about 2 g. of protein; a white bread (70% extraction) contains rather more carbohydrate—16.8 g. per ounce; and "hovis" bread less, at 13.35 g. per ounce. Patients do not often change the kind of bread they eat, and in any case the small difference in carbohydrate content of different breads does not matter when the diet contains, as it should do, 150–200 g. or more of carbohydrate. If, however, a patient who, say, eats only hovis bread travels abroad and eats the same amount of white bread exclusively, the urine might contain a little sugar, which would necessitate 2 or 4 units more insulin. On returning to the hovis bread slight symptoms of hypoglycaemia might occur unless the dose of insulin was promptly reduced.

Treatment of Congenital Absence of Rectum

Q.—What recent advances have there been in the treatment of congenital absence of the rectum? Is there any satisfactory alternative to a permanent colostomy?

A.—Whereas it was formerly believed that there was no satisfactory alternative to colostomy in cases of imperforate anus with absence of the rectum, it does now seem that restoration of continuity with a properly functioning anus is possible in some cases. Clearly such restorative operations are only possible where the sphincteric apparatus has developed normally. Under these conditions there are some authorities who state that repair can be effected by a purely perineal approach, even without a preliminary colostomy. The rectal pouch has to be freely mobilized so that it can be brought down to the anus without tension; from the technical point of view the operation can be very difficult and may be succeeded by stricture at the suture line. At the best, a functioning anus will be attained; at the worst, the patient may be left with a perineal colostomy, possibly associated with stricture formation. To facilitate repair in those cases where the rectum ends blindly at the pelvic floor a synchronous combined abdomino-perineal procedure has been described.² It must be emphasized, however, that expert opinion in this country is inclined to the view that, desirable though they may be, these operations are often not

feasible. In general, restorative operations should be undertaken as soon after birth as possible, and it is most unlikely that the sphincteric apparatus would function.

Physical Characters Associated with Schizophrenia

Q.—With what physical characteristics is a tendency to schizophrenic illness genetically associated? Brown eyes, for instance, appear to be rare in schizophrenics.

A.—So far as is known there is no single physical trait genetically associated with schizophrenia. There is evidence that tuberculosis is abnormally frequent, not only among schizophrenics themselves, but also among their brothers and sisters; but parallel investigations have failed to show any increased tendency to schizophrenia among the tuberculous or their relatives. It may be that schizophrenics in this country are rather rarely brown-eyed; but it must be remembered that schizophrenia is no less frequent in countries such as Greece and Italy, where the bulk of the population is brown-eyed, than it is here.

Television and the Eyes

Q.—Is television dangerous to the eyes?

A.—No. If any significant refractive error is present, correcting spectacles should obviously be worn.

NOTES AND COMMENTS

Pills for Bankrupt Smokers.—In reply to a question about the dosage and frequency of administration of the pills for preventing the desire to smoke ("Any Questions?" January 12, p. 118), OUR EXPERT suggests that 5-gr. (0.32-g.) pills might be taken three or four times a day for as long as required.

Multiple Myelomatosis.—Dr. A. PINEY (London) writes: The answer to the question on multiple myelomatosis ("Any Questions?" February 9, p. 340) is a little misleading in its description of the diet during treatment with stilbamidine. The paper in which this was advocated came from the United States, and the diet suggested was one which for that opulent country was low in protein but for us is at about the level of our rations. There is thus no reason why patients with myelomatosis should have their protein intake reduced below British standards. Further, the answer does not mention that preliminary treatment with stilbamidine greatly increases the radiosensitivity of the neoplastic cells.

Angina in Cold Weather.—Dr. G. BILSBARROW (Ontario, Canada), commenting on a reply to a question asking whether it would be advisable for a lady suffering from angina pectoris, aggravated by cold, to emigrate to Ontario ("Any Questions?" January 12, p. 118), writes: Having been in practice in North-west Ontario for the past three years, where a temperature range of 90° F. (32.2° C.) in summer to 40° F. below zero (–40° C.) in winter is common, I have not noted any increase in symptoms of angina among our patients. Most of the work here is outdoors and we have a normal incidence of ischaemic heart disease, but this is neither increased in winter nor is there any increase in the incidence of symptoms among known cases.

THE DURHAM DISPUTE PROGRESS HALTED

Durham County Council is still trying to impose an indirect form of compulsion on the doctors in its employment. A recommendation by its own emergency committee that the relevant regulation of the council should be waived has been referred back for further consideration. It seems that the Emergency Committee, at the private meeting of the labour group which preceded the council, were unable to persuade their political colleagues of the wisdom of abandoning the closed-shop policy in regard to doctors.

The B.M.A.'s dispute with the Durham County Council thus regrettably continues. The position was discussed at a meeting of the B.M.A. North of England Branch Council at Newcastle-upon-Tyne on March 1, attended by Dr. E. Grey Turner (Assistant Secretary). It was also considered by the Public Health Committee on March 7. Meanwhile, four vacant appointments in the Durham County medical establishment remain unfilled.

Professions get Together

On March 4 representatives of the following organizations met at B.M.A. House: the B.M.A., the Royal Colleges of Nursing and Midwives, the British Dental Association, the National Union of Teachers, and the Engineers Guild. According to a statement issued, they decided to recommend to their organizations the establishment of a joint emergency committee to review the position created by the recent action of Durham County Council affecting the professions in relation to membership of trade unions and professional organizations, and to consider further action.

Indirect Compulsion

Under the regulation an application for extension of sick leave with pay beyond the period of contractual entitlement must be made through "the proper organization of which the employee is a member." While this regulation does not involve actual coercion of any employee to join an organization, it is an indirect form of compulsion: for an employee would lose certain benefits if he decided not to comply with the regulation. These views were put to the council's Emergency Committee by the Secretary of the B.M.A. when he went with a deputation to Durham on November 19, 1951 (*Supplement*, November 24, 1951, p. 225).

Advertisement Ban

This *Journal* will continue to refuse to publish advertisements of vacant medical appointments under the county council until the situation changes.

The Association's policy has always been to resist the attempts of any employing body to compel its employees

ADJUDICATION NOW MARCH 12

Mr. Justice Danckwerts has decided that the adjudication shall begin on Wednesday, March 12, at 10.30 a.m. It will be in the Chancery Court, London. This date is two days later than the one announced in these columns last week.

to belong to any organization—whether the B.M.A. or any other. The Association was successful in getting Durham to rescind its requirement that doctors in its employment should belong to an organization as a condition of employment, and it will continue to resist this indirect form of compulsion.

The view of some of the Durham councillors at the November meeting was that since the payments in question are *ex gratia* the council is entitled to lay down the procedure to be followed in applying for them. The Association contends that it is just because the payments are *ex gratia*, and a doctor's professional organization is not in a position to argue with the council about them, that the procedure proposed can be of no practical advantage, quite apart from the question of principle involved.

Penalty on Professional Freedom

And as to the principle, this was explained to Durham County Council in a letter from the Secretary of the B.M.A. (*Supplement*, December 1, 1951, p. 233) in these words: "What we do not admit is that the council is entitled to prescribe a procedure of application the effect of which, in a particular case, might be to penalize a member of our profession who, in accordance with his professional freedom, remained outside the membership of professional organizations."

Further Stage at Chester-le-Street

The Chester-le-Street Rural District Council, which lies in County Durham, has carried the closed-shop policy a long stage further than the county council. It is understood that the labour group, which is in an absolute majority on the rural district council, requires that all employees shall belong to trade unions affiliated to the T.U.C. The rural district council has accordingly refused to approve the appointment of its own M.O.H. as joint M.O.H. of the rural and urban districts of Chester-le-Street on the grounds that he declined to answer questions about trade union membership. In a Press statement on March 1 it was revealed that he is not a member of a trade union and "has no intention of joining one simply to meet the wishes of the council."

1s. ON PRESCRIPTIONS**MEETING WITH MINISTER**

A deputation from the G.M.S. Committee is to meet the Minister of Health to draw attention to certain difficulties about levying the 1s. on prescriptions. March 18 is the provisional date for the meeting. It will be at the House of Commons.

The Committee is primarily concerned with the fact that the scheme makes dispensing doctors act as intermediaries for the Inland Revenue. The Minister has been told that the Committee is disappointed it had not been given an opportunity of expressing its views on the detailed application of the scheme at an earlier stage. The Committee considers the present proposals to be impracticable in country districts, and also that they will cause hardship to patients being treated for chronic disabilities.

THE N.H.S. NUMBERS**G.M.S. COMMITTEE NOT CONSULTED**

Since the National Health Service began the Ministry has invariably consulted the G.M.S. Committee before giving effect to any points of policy affecting general practitioners in the Service.

An unfortunate precedent has been created by the issue of E.C.L. 6/52, dated February 21, dealing with the revised procedure to be introduced as a result of the abolition of identity cards (*Supplement*, March 1, p. 80). Not only was there lack of consultation on this important circular but its contents disclose that a further burden is to be placed upon the general practitioner. It appears that, although identity cards have been abolished, practitioners "in their own interests" are advised in future to obtain the N.H.S. number of any persons seeking acceptance on their lists and to note these numbers whenever requested, as, for example, on maternity and temporary-resident forms.

Strong Protest Lodged

Already practitioners are asking whether there is any legal force behind the requirement and whether the words "in their own interests" mean that a doctor who cannot supply the information—possibly because the patient will not divulge it—will receive no payment for the service he has provided. The G.M.S. Committee has lodged strong protests about the issue of this E.C.L. and has asked for an early opportunity to discuss its contents.

Scottish News**REGISTRARS' GROUP—SCOTTISH WESTERN REGION**

The Third Annual General Meeting of the Group will be held in the Lister Theatre of the Royal Infirmary, Glasgow, on Thursday, March 20, at 7.30 p.m. All registrars are invited to attend.

Among appointments made by the Secretary of State for Scotland to the Standing Advisory Committees of the National Health Service are the following: *Standing Advisory Committee on Hospital and Specialist Services*: Miss S. I. McIntosh, almoner, Western General Hospital, Edinburgh, and Mr. W. A. Stevens, secretary and treasurer, Board of Management for County and City of Perth General Hospitals, have been appointed; Mr. J. Brownlee, secretary, Dumfries and Galloway Royal Infirmary, has been reappointed. *Standing Advisory Committee on Health Services in the Highlands and Islands*: Dr. T. Scott, Inverness, has been appointed; Dr. A. Lamont, Inverness, Mr. G. McIver, Member, Sutherland Executive Council, and Provost A. J. Mackenzie, Stornoway, have been reappointed.

HEALTH SERVICE ESTIMATES UP

The Civil Estimate for the Health Service for 1952-3 is £358.20m. for England and Wales and £44.08m. for Scotland. The total is £402,286,500. This is £2.78m. more than last year's estimate, which was £399,506,500.

SAFEGUARDING PUBLIC HEALTH M.O.s

Among the problems that come to B.M.A. House for solution are many of a personal or individual nature that cannot be publicized. But three unusual cases which have recently occurred deserve some mention.

They are concerned with the introduction of certain so-called private Extension Bills. These Bills provide for the extension of various local authorities, which, if the Bills go through, will include parts or the whole of other county districts. Some of the public health medical officers of these districts might find their position jeopardized, and the B.M.A. is now acting to protect them. Some adjustments of local-authority boundaries can easily have an adverse effect on the employment of public health doctors. The position of a medical officer can be safeguarded by providing either that his services are continued without loss of status and remuneration or that adequate compensation is made. The Association is at present advising along these lines.

GENERAL MEDICAL COUNCIL

A meeting of the General Medical Council was held on February 26, with the PRESIDENT, Dr. David Campbell, in the chair.

Major W. J. Anstruther-Gray, M.P., was introduced by Sir Henry Wade and took his seat as a Crown nominee for Scotland. Major Anstruther-Gray was also appointed to fill the vacancy on the Medical Disciplinary Committee caused by the resignation of the Rt. Hon. Florence Horsbrugh, M.P. The Medical Act, 1950, requires that at least two members of that Committee must be persons who are neither registered medical practitioners nor the holders of qualifying diplomas. The other member who fulfils this requirement is Lord Nathan.

Address to the Crown

The President moved that an Address of condolence to Her Majesty the Queen on the death of the late King and of congratulation to Her Majesty on her accession be transmitted to the Secretary of State. The motion was carried, the members standing. The Address began with a reference to the loss which has recently befallen the Royal House. "Our grief is shared by all the subjects of Your Majesty, but felt by none more deeply than the medical practitioners registered in this country. . . . The burden of illness and pain which his late Majesty so courageously bore was a source of especial concern and anxiety to the members of our profession; and the indomitable courage and resolution with which he faced every misfortune aroused our devoted admiration." The Address went on to refer to the late King's personal interest in the art and science of medicine. "His reign will be remembered for the further extension of the health services of the country to all classes of the community, and for undertakings and achievements of medical research exemplifying, in his own words, 'that spirit which inspires the State and science to work together for the health and happiness of mankind.'"

In tendering their humble duty to Her Majesty the Council referred to the fact that she had been pleased to honour the profession of medicine by assuming a personal connexion with more than one of the Corporations represented on the Council, and that many tokens

had been given by her of a close and constant interest in the health and welfare, at home and overseas, of the people who were now her loyal subjects.

Commonwealth Diplomas

The PRESIDENT presented a report of a special committee set up by the Council to deal with provisional and full registration under the Medical Act, 1950. He said that one of the first tasks of the Committee was to consider, following a letter from the Commonwealth Relations Office, the registration under the Medical Acts of practitioners holding Commonwealth diplomas. The Commonwealth Relations Office had suggested that the Council should furnish a memorandum for transmission to the Commonwealth High Commissioners concerning the effect of the recent Medical Act and of the Council's regulations on applications for registration made by virtue of Commonwealth diplomas and also on the procedure for exchange of information, including lists of approved hospitals, which might assist the Council in reaching decisions on such applications.

Dr. Campbell went on to say that in preparing the memorandum the Committee had endeavoured to indicate as far as was possible at this stage the manner in which applications might be dealt with by the Council. It was not practicable to specify any general criteria by which applications based on experience other than experience acquired by 12 months' service as house-officers in suitable hospitals would be determined. It would be necessary to set up machinery to ensure that all applications of this nature were considered on their merits and decided expeditiously, and for this purpose the Committee proposed that a special committee should be set up consisting of a physician, a surgeon, a member engaged in general practice, and the President *ex officio*, for considering applications for full registration which did not come within the general resolution of the Council.

House-Officer Experience

The memorandum prepared by the Committee, a lengthy document, was laid before the Council. It suggested that prospective applicants holding Commonwealth diplomas might be expected to fall into one or other of three categories: (1) those who had acquired experience for not less than 12 months as house-officers under compulsory internship schemes substantially equivalent to the scheme in this country; (2) those who had had this experience as house-officers, but not under any compulsory internship scheme; and (3) other applicants. The President remarked that two Commonwealth territories—the Union of South Africa and New South Wales—had already brought into operation compulsory schemes requiring a period of house-officer service as a normal condition of full registration in the territory. As years went on most Commonwealth countries would no doubt fall into line.

It was the Council's general intention that full registration should be accorded to an applicant holding a recognized Commonwealth diploma who produced satisfactory evidence of such service. In the case of applicants who had acquired 12 months' experience as house-officers, but not under any compulsory internship scheme, the Council would take into consideration satisfactory service in employment in a resident medical capacity in any hospitals which the appropriate medical authority considered satisfactory, and to this end it was proposed to make available to the bodies concerned further particulars of the arrangements for approval of hospitals and of particular posts and combinations of posts obtaining under the new procedure in this country. As for the applications not comprised in these categories, where experience for 12 months as house-officers in suitable hospitals had not been acquired, it was possible that the applicant might have had experience in other clinical posts or in general practice or as a medical officer in the armed Forces, but the Council could not see its way to specify in general terms the criteria by which applications based on such experience would be determined. Applications would be considered sympathetically on their merits.

Sir Bennett Hance expressed on behalf of the Commonwealth Relations Office its indebtedness to the Committee for the trouble which had been taken and for the very liberal spirit in which

the memorandum had been drafted. He was sure that it would materially lessen the complications that might otherwise arise.

The memorandum was unanimously approved.

Provisional Registration

The President said that the special committee had also considered the nature of the evidence on selection for employment which applicants for provisional registration under the Medical Act, 1950 (sect. 6), should be required to submit. The regulation of the Council called for evidence satisfactory to the registrar of the Branch council concerned that the applicant had been selected for employment as a house-officer within the meaning of the Act and had paid the appropriate fee (normally not exceeding five guineas) for provisional registration. The Committee had drafted a form of certificate to be signed by an authorized officer of the university or other corporation which had granted the qualifying diplomas. But it was thought that in addition to this formal evidence of employment in a resident medical capacity licensing bodies and medical schools would desire to receive information concerning the duties attached to the post for which the student had been selected, the duration of the employment, and the date on which the applicant was to take up duty. It had therefore prepared a more extended form of certificate providing for the insertion of these particulars.

The Council approved the form of the first certificate and agreed that the suggestion concerning the fuller certificate should be brought to the notice of licensing bodies and medical schools.

In some brief discussion in the Council Dr. J. G. McCRIE asked whether it was the fact that the Ministry of Health was taking steps to ensure that posts approved by licensing bodies were in fact restricted to applicants of a particular category. Sir SYDNEY SMITH said that it was necessary to ensure that these posts were available; these people must not be left "hanging about." Dr. McCRIE said that, while there might be the posts in existence, powers might be lacking to the hospital committee to fill them. Major ANSTRUTHER-GRAY said that he would make inquiries on that point.

In reply to a question whether persons provisionally registered could, without breaking the law, serve as locum-tenents, the Legal Assessor pointed out that, while such a person might not be breaking the law, he would, not having served his year, be subject to certain disabilities. He could not give a certificate, and therefore would not be very helpful as a locum-tenent.

The President announced that legislation giving effect to arrangements previously made between the United Kingdom Government and the Government of the Republic of Ireland concerning the British Medical Act, 1950, had now been passed in Ireland, and the Irish authorities were prepared to adopt January 1, 1953, as the operative date for the introduction of arrangements for compulsory intern service.

Disciplinary Business

The Council dealt with two disciplinary cases in which previously, when the whole Council was sitting as the disciplinary body, judgment had been postponed. One was the case of Dr. Roger St. Aubyn, registered as of Redcliffe Square, London, S.W., against whom convictions had been proved in June, 1949, and in September, 1950, of driving a motor vehicle while under the influence of drink. Dr. St. Aubyn appeared and produced four testimonials, and the Council did not see fit to erase his name, and closed the case. The other was the case of Dr. Frederic Syson, registered as of Horsforth, Leeds, against whom certain convictions for misdemeanours, the first in 1945, of drunkenness, had been found proved. The inquiry and, later on, the judgment had been postponed on several occasions owing to Dr. Syson's illness. Dr. Syson now appeared and presented certain testimonials, and here also the Council did not see fit to erase the name, and closed the case.

MEDICAL DISCIPLINARY COMMITTEE

Later on the same day, February 26, a meeting of the Medical Disciplinary Committee was held, with Dr. DAVID CAMPBELL in the chair.

The CHAIRMAN reported that Dr. Arthur James Daly, whom the Committee had judged in November, 1951, to have been guilty of infamous conduct in a professional respect, and had determined that his name should be erased from the *Register*, had lodged a petition of appeal under sect. 20 of the new Act. He also reported that an Order in Council had been approved granting leave to Dr. Jack Michael Sinclair to withdraw the appeal brought by him against the determination of the Committee in July, 1951, that his name should be erased from the *Register*, and that the determination of the Committee had thereupon taken effect as from the date of the Order.

Non-appearance of Practitioner

The Committee considered the case of Harold Stanley Groves, registered as of Blagreaves Lane, Littleover, Derby, against whom at a previous sitting the Committee had found proved convictions in October, 1949, and January, 1951, at Derby of being under the influence of drugs in the one case and of drink in the other whilst in charge of a motor-car. The Committee had previously postponed judgment to the present session. The Council's Solicitor said that he had written the usual letter to Dr. Groves but had received no answer. A second letter was written to his solicitors, who stated that they had no instructions. Dr. Groves was not present at the hearing nor was he represented by counsel or solicitor. Mrs. Groves, however, appeared on his behalf and told the Committee that her husband was a very sick man, but refused to see either a doctor or a solicitor. He had given up practice, he was well on in the sixties, and she asked that he might be allowed to go into honourable retirement. The Committee decided to postpone judgment until the May session, and in the meantime advised Mrs. Groves strongly to impress upon her husband the desirability of obtaining the names of professional colleagues or other persons who would be prepared to testify on his behalf.

Conviction for Attempt to Procure Miscarriage

The Committee considered the case of Dr. Charles Locksley Bikitsha, registered as of Butterworth, Cape Province, but lately practising in Birmingham, who appeared on the charge that in July last at Birmingham Assizes he was convicted on an indictment that in April, 1951, with intent to procure the miscarriage of a woman he had unlawfully used an instrument or some other unknown means and had unlawfully administered and had caused to be taken by her a poison or other noxious thing, and that with the same intent, also in April, he had unlawfully administered a poison or other noxious thing to a woman. He had been ordered to be imprisoned for two years on each of four counts, the sentences to run concurrently.

Dr. Bikitsha was defended by Mr. A. P. Marshall, Q.C., and Mr. M. Talbot. Mr. Marshall at the outset asked that the case be taken *in camera* for the reason that Dr. Bikitsha was heir apparent to the paramount chief of a tribe in South Africa, and the publication of a case of this kind might have unfortunate repercussions in that part of the world. The Committee, however, decided to hear the case in public.

The conviction having been admitted, Mr. F. P. Winterbotham, the Council's solicitor, said that a woman named Margaret Malone, who lived four miles from the doctor's house in Birmingham, found that she was pregnant. She had had two children and wished to avoid another pregnancy. With a friend she visited Dr. Bikitsha, and to gain his sympathy told him that a coloured man was responsible for her condition. She paid him £10 and he examined her, using an instrument, and handed her a prescription for ergometrine. On the following day she was taken ill and sent to hospital, and a puncture of the womb by an instrument was discovered. The doctor was interviewed, and said that the woman when he saw her was threatening

abortion. The other woman in respect of whom a charge was brought was married to a coloured man. In this case the prescription supplied contained the drug ergot.

Mr. Marshall, in defence, said that the circumstances in this case were most unusual. At the assizes his client was charged on an indictment with ten counts involving four women. Two of the counts dealt with offences alleged to have happened in September, 1950, and the others with events in April, 1951. The counts relating to the first two offences were withdrawn by the prosecution in the course of the trial, and he was found guilty on only four of the counts. Dr. Bikitsha was 35 years of age. He was born in South Africa, where he was heir apparent to the paramount chief of the Abambo tribe. He was at Edinburgh University from 1936 to 1941 and graduated in medicine there, and took the L.M. diploma after study at the Rotunda Hospital, Dublin. He intended to specialize in obstetrics and gynaecology. He set up in practice in a newly developed district of Birmingham, and had a list of over 3,000 N.H.S. patients and about 100 private patients.

Coming from South Africa, he knew the helpless condition of half-caste children, and that motive was operating when Malone told him she was pregnant by a coloured man. The evidence both of Malone and her friend was that when the doctor was asked he said, "I do not do that sort of thing." He eventually examined her and discovered that she was actually aborting; before she went to him she had done several things to bring it about. Medical evidence was given for the prosecution by three doctors, one of whom stated that a macerated foetus of 10 or 12 weeks' development was delivered at the hospital. Mr. Marshall said that he must remain loyal to the verdict of the jury, but he maintained that all that Dr. Bikitsha did was according to the accepted way of dealing with an impending abortion. In the second case, that of a woman who was married to a coloured man, all that he did was to inject penicillin and physostigmine; in fact the examination of the vagina was the same as that carried out by other doctors when the woman had had her previous children. On a charge of using an instrument on her he was found not guilty. She came with a story of missing her periods and the physostigmine was given as a test for pregnancy.

Mr. Marshall further said that Dr. Bikitsha had a remarkable position among the coloured community in Birmingham. They knew of his genuine attachment to the interests of his race, and he was consulted by them on matters of this kind. He put in a large number of testimonials on his behalf, four of them from doctors (two of them fellow Africans), and from nurses and others. If he was struck off the *Register* there would be a corresponding erasure of his name in South Africa, and the high degree of skill he had acquired would be lost to the people of his own race.

The Rev. Norman Power, who was vicar of the parish in Birmingham in which Dr. Bikitsha carried on his practice, gave evidence on his behalf, saying that the doctor attended himself and his family, and he had never known a doctor more beloved in the district where he worked. He never spared himself for his patients. He recalled one case in which a mother was in a serious condition after confinement and he called to see her 13 times in 24 hours. The people were longing for the time when he would be able to resume his work among them. There was a feeling of great indignation in Birmingham concerning some aspects of the trial. After the verdict a number of friends of the doctor had organized a petition to the General Medical Council. This petition was put in; it contained 2,739 signatures, and the signatories included the parents of 1,000 children.

After a deliberation *in camera* the Committee found the conviction proved and directed the Registrar to erase from the *Register* the name of Charles Locksley Bikitsha, subject to his right of appeal within 28 days to the Privy Council.

Supposed Offence

A practitioner came before the Committee on the charge that in October last he had been convicted at a London police court of behaving in a manner reasonably likely to offend against public decency, contrary to the Hyde Park regulations, and had been fined £5. The practitioner attended with his solicitor, and it was explained that the supposed offence was one of which he was entirely innocent. He was molested by another man and before he could break away two police officers arrested them both, and both were fined. The practitioner, who was a stranger to London, was told by the police officer that if he pleaded guilty there would be no publicity, and in the distress of the moment, having no legal advice, he did so, but publicity nevertheless

was given to the case. The practitioner said that no thought of committing an offence had ever entered his mind, and two medical colleagues testified to his lifelong probity. The Committee, while accepting the fact of the conviction, dismissed the case.

Questions Answered

Schedule A and Surgery

Q.—*I am a general practitioner, and have surgery premises separate from my private house. Because I use my private house partly for professional purposes, I am allowed half the rates (of my private house) as expenses for income-tax purposes. In view of this, am I assessed for Schedule A on my private house on the full rateable value or only half the rateable value?*

A.—Where the residence is owned by the practitioner there is of course no actual "rent" paid, but in calculating the total allowable expenses there can be included the appropriate fraction of the net annual value as assessed to income tax (usually similar in amount to the rateable value). In other words the practitioner can treat as "rent" the amount on which the Inland Revenue assesses him as owner.

Board of Locum

Q.—*May I claim an income-tax allowance for the board and lodging of my locum when I am away?*

A.—The cost of providing board and lodging for a locum-tenent is an essential part of the total expense, and is deductible in the same way as the remuneration payable to him. There is no standard rate on which that cost can be calculated, since so much depends on the actual facts. For instance, in the absence of the principal and his family the additional expense incurred by reason of the presence of the locum-tenent may be mainly confined to food, laundry, and service.

Diagnosis of Pregnancy

Q.—*I have been informed by the clerk of the local executive council that where a diagnosis of pregnancy only is made, and the woman is referred to an antenatal clinic for subsequent care and confinement in hospital, this forms part of the general medical services and that therefore no claim is admissible on Forms E.C. 24 or 24A. Is this correct?*

A.—The ruling given is correct (see General Medical and Pharmaceutical Services Regulations, 1948, Part V, Section 19, as amended).

Entertainment Expenses

Q.—*Can I claim for income-tax purposes entertainment expenses, representing the estimated cost of entertaining patients and consultants, and also other local doctors, meeting in their houses to discuss questions concerning the profession?*

A.—In a case decided last summer it was held in the High Court that expenditure on hospitality coupled with advice for which a fee was charged could be allowed as professional expenses. It should be noted that in that case the entertainment took the form of luncheons at which the client's business was discussed and advice was given. The decision would not be sufficient support for a claim to deduct entertainment costs incurred when consultations were not held and advice was not given. We have no knowledge of the allowance of expense incurred in such circumstances.

Returning from Abroad

Q.—*I wish to return to live in Britain after 26 years in Africa. I shall have a Colonial Medical Service pension plus savings and also six months' leave on full pay from my present employers. If I return in the second half of Britain's financial year, do I escape income tax during that year? Will my savings be taxed?*

A.—British income tax will not be levied on the savings, though it will attach to the income from the savings as from the date of arrival in this country. Returning in the second half of the financial year will not carry exemption for that half-year: the exemption which is granted in such circumstances applies only to persons coming to the United Kingdom with no intention of residing here.

Heard at Headquarters

The Adjudication Court

A visit to Chancery Court III, over which Mr. Justice Danckwerts presides, suggests that those who attend the adjudication proceedings will not be over-furnished with elbow room. Apart from the seats reserved for counsel and solicitors and others engaged in the case, and a small box for the Press, there are only two long benches across the width of the court, each seating perhaps a dozen people, for the accommodation of the public, and, unlike some other courts in the building, there is no gallery. The two previous courts of inquiry were held in the large room at the Ministry of Health, then in Whitehall, where there was ample accommodation. In both of them the proceedings were less of a judicial pattern than may be expected on the forthcoming occasion. The second of them, in 1937, lasted four days, and was prolonged because the Ministry at the last moment produced some unexpected witnesses—who gave such an extraordinary account of conditions in general practice that the Association decided forthwith to bring forward rebutting evidence, which it did to excellent effect.

Marketable Item

Over the last 20 years American people have spent about 4% of their "consumer budget" on medical care, according to the American Bureau of Medical and Economic Research (*J. Amer. med. Ass.*, 1951, 147, 1354). Medical care as a saleable commodity is discussed in this article. The demand for it is said to have been small not because people could not afford more but because they preferred to spend their budgets in this manner. "To-day, however, the widespread availability of hospital and medical insurance makes medical care a readily marketable item." In fact, for the price of a packet of cigarettes a day a family can purchase a Blue-Cross-Blue-Shield membership which will pay the bulk of hospital and in-patient bills.

Hansard and Anatomy

Lord Webb-Johnson treated his fellow peers to an interesting dissertation the other day—the occasion was the motion to adjourn the House of Lords as a mark of respect to the memory of Lord Addison—on the value of eponyms in medical teaching. *Hansard* made a very good effort to follow him through Poupart's ligament, and Arnold's nerve, and the circle of Willis, but made a slip when, after a reference to Galen, Fallopius, and Eustachio, Lord Webb-Johnson was made to say, "These are examples of *Indian* anatomists." Again, in referring to medical men who have become Prime Ministers, Lord Webb-Johnson is reported as mentioning Sir Charles Tupper, Sir Starr Jameson, Sir Godfrey Huggins, and "Earl Page," as though Sir Earle Page, for a short time Prime Minister of Australia, was a member of the British peerage. *Hansard* is such a

daily miracle that one gets a mischievous satisfaction when it just falls short of bringing off the trick.

New Nomenclature

The report of the Joint Committee of the B.M.A. and the Magistrates' Association on the illegitimate child has been appreciatively received for the humane and understanding document that it is. Some of its recommendations have to do with nomenclature, which is not unimportant. In this field, as already in mental disorder and indigence, there is a movement away from the old crude and cruel descriptions. The terms "lunatic" and "pauper" have passed out of currency, and the terms "illegitimate child" and "bastard" should follow them. The difficulty is to know what to put in their place. "Natural child" seems to be the least objectionable of the terms suggested, but it conveys an odd reflection on legitimate children. The Committee also objects to the term "putative father," holding that simpler terms should be substituted.

Foot Clinics

The question of foot clinics is giving rise to some controversy between the Ministry of Health and the London County Council. The Minister has decided not to approve the provision by local health authorities of additional foot clinics for the general population, pending consideration by him of the part which chiropody should play in the National Health Service. The London County Council, on the other hand, is impressed by the inadequacy of the foot service in many parts of London. The Council has 26 foot clinics, but they are situated in only 15 of the 28 Metropolitan boroughs. There is no clinic in the City of London or in the East End or in South-west London. Representations have been made to the Minister, who has replied that in present financial circumstances he cannot agree to any extension of the service. It is proposed to pursue the matter further by a deputation from the Council, having in mind the report of the Departmental Committee in April last that local authorities should be enabled to provide chiropody in the National Health Service, possibly under section 28 of the Act.

Surgeons and the Apocrypha

The Royal College of Surgeons made a very dignified event of the unveiling of the Hunter tablet at St. Martin-in-the-Fields, and Sir Gordon Gordon-Taylor was interesting and eloquent in the pulpit, especially in his description of the macabre search for Hunter's coffin in the vaults of the church, when 3,204 coffins were exposed before Hunter's was discovered. What interested one listener at least was the choice of the lesson read by the President of the Royal College. It was from the Apocrypha; the canonical scriptures do not seem to offer much that is suitable for such occasions. Such references as there are to the medical profession in the Bible are not always complimentary. There is the case of Asa, for example, who "turned not to the Lord, but to the physicians; and Asa slept with his fathers." In the Apocrypha, in the book of Ecclesiasticus, there is the famous passage, "Honour the physician according to thy need of him," which has been read on innumerable occasions at B.M.A. church services, but that refers only to the physician and the apothecary, not to the surgeon. The lesson chosen at St. Martin's was from the seventh chapter of the Wisdom of Solomon, which incidentally mentions 10 months as the duration of pregnancy. But it is a fine passage—"As I learned without guile I impart without grudging"—with the true Hunterian ring.

National Formulary, 1952.—The second edition of the *National Formulary* will be published on March 28. Copies will then be available at 4s. 6d., or, if interleaved, 7s. 6d. Copies of the new issue will be distributed to practitioners after a sufficient time has been allowed for wholesale and retail pharmacists to make adjustments to their stocks. The effective date after which the new edition will replace the *National Formulary*, 1949, will be June 1.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Glasgow Graduates Dinner

SIR,—In accordance with preceding practice we are taking an opportunity of reminding those members of the Representative Body who are Glasgow graduates that the Glasgow Graduates Dinner will be held in the Royal Hibernian Hotel, Dublin, on Saturday, July 5, 1952, at 7 for 7.30 p.m., when Dr. Peter Lyle will occupy the chair. The cost of the tickets will be 30s. per head, including aperitifs.

Certain distinguished guests have already indicated their willingness to attend, and it is hoped that all Glasgow graduates and their ladies present in Dublin during the Annual Meeting will take this opportunity of renewing friendships of student years and of savouring once again the living spirit of our Alma Mater. Tickets will be obtainable from the organizing secretary, whose name appears below.—We are, etc.,

PETER Y. LYLE,
Chairman.

ROBT. FORBES,
Organizing Secretary, Tavistock House South,
Tavistock Square, London, W.C.1.

Health Service Charges

SIR,—The charge of a shilling for each prescription is unjust, because the patients are not responsible for the cost of the medicine. That depends upon the prescription given to them by the doctor, and they cannot prescribe for themselves.

Its collection presents many difficulties. Neither the doctors nor the chemists are willing to act as tax-gatherers. The various exemptions will lead to much confusion and extra work and worry for the chemists. Already organized resistance from miners and engine drivers has started and is likely to spread, as the scheme is very unpopular with the general public.

When the National Insurance Service started in 1912, 2s. was allowed for drugs and dispensing for each insured person per year. This was sufficient for a few years because the panel doctors had, previous to the Act, been accustomed to dispense their own medicines. The cost of drugs and appliances now is above 17s. for each person per year. There is urgent need for economy, and this can be brought about only by the full co-operation of the doctors. For this purpose it is necessary for them to have up-to-date information of the average cost of the prescriptions of all the doctors in the area. This was available for each area under the National Insurance Service, but it is not now available for the executive councils. The pricing bureaux are about 10 months behind. This is due to the difficulty in obtaining clerical staff while the remuneration is not comparable with that for corresponding posts in the neighbourhood. This must be remedied as soon as possible if we are to deal efficiently with the problems of economy.

I have a logical plan which should not penalize the doctors or patients, but should lead to economy and prevent waste. In outline it is that each doctor should pay one-tenth of the cost of his own prescriptions, and in compensation be paid a higher capitation fee. In consideration for your valuable space I shall not go into details now.—I am, etc.,

Reading.

S. GILFORD.

SIR,—I should like to draw attention to a point which has so far received no mention in your reports or correspondence columns. Until now the replacement of surgery stocks of such things as dressings, antiseptics, and emergency injections has been a simple matter. The doctor writes a prescription for a suitable quantity, in the name of a patient

on whom part of his stock of the drug or dressing has been expended, and from time to time himself presents these prescriptions to the chemist, thus maintaining his supplies.

When the shilling charge comes into effect, it will no longer be so simple. The doctor must do one of four things: (1) Insist that the patient collects his own bandage, strapping, or injection from the chemist before treatment can be given. This is most inconvenient, and in the case of emergency, such as a bleeding hand, quite impracticable. (2) Give the patient the prescription for the material used after giving treatment, and ask him to bring it back to the surgery later. In most cases the patient will not do this. (3) Charge the patient a shilling, and present the prescription himself. This is open to the same objection as that raised by the G.M.S. Committee to the collection of money by dispensing doctors. In urban areas it could also give rise to misunderstanding and allegations that the doctor had charged a fee. (4) Pay the shilling himself in order to make good his stocks. This is equivalent to the doctor's subsidizing the patient's treatment, and would involve an additional and quite unjustified practice expense.

The payment of 2s. 6d. per 100 patients which, I believe, is at present made by executive councils for the supply of emergency drugs is surely not intended to cover such everyday instances of the use of dressings and medicaments stocked by the doctor, but only the occasional sleeping tablet or draught given after the shops are closed.

Professor Dunlop and his colleagues (*Journal*, February 9, p. 292) described a Form E.C.10A said to be available to practitioners for ordering supplies for surgery use. I have never encountered this form in England and Wales. What is needed is, in fact, such a form, with a prescribed list of items that may be ordered on it and, of course, exempted from the shilling charge. I see no other alternative if inconvenience to the patient or injustice to the practitioner is to be avoided. Abuse of the facility would be unlikely, and excessive prescribing on such a form could be easily checked, as the forms could be kept apart from the ordinary E.C.10s.—I am, etc.,

Marlow, Bucks.

ARVID SAUDEK.

SIR,—I am surprised that no one has so far suggested that the doctor should keep the shilling paid for each prescription.—I am, etc.,

Dorchester, Dorset.

C. HOLLINS.

SIR,—If as a result of the abuse of the Health Service the Government is financially embarrassed to the extent that a shilling has to be charged on every prescription (the chemist being paid per item), then surely the dispensing doctor is equally embarrassed himself, as he is paid on a capitation basis. It is he who is at a financial loss and not the Government. It seems to follow that if he charges the shilling it should go into his own pocket and not into the Treasury. I am not a dispensing doctor.—I am, etc.,

Llantrisant, Glam.

J. C. R. MORGAN.

SIR,—Your correspondents have mentioned several of the points against the 1s. prescription charge. So far they have not mentioned the injustice to those who, having paid insurance for many years, perhaps since 1911, had retired before 1948 with a right to medical benefit, including medicines, for the rest of their days. For the first time in perhaps 40 years these people will have to pay for their medicines, for which they have already paid by their insurance contributions. It may be a consolation to some of them that they can, if necessary, apply as paupers for repayment.

If doctors cannot restrain greedy or importunate patients, no tax will deter them. It is our responsibility to give the patients what they need, not what they demand, although it must be admitted that the capitation system of payments is a temptation to compete, like grocers, for registrations.—I am, etc.,

Maldon, Essex.

D. CARGILL.

Birmingham Replies

SIR,—I have been instructed by the Birmingham Executive Council to ask you to publish the following observations in reply to the letter from Dr. D. R. Prem which appeared in the *Supplement* of February 9 (p. 55) under the heading "Unhelpful Attitude."

(1) In July, 1948, when Dr. Prem requested the executive council to support his application to the Birmingham Corporation for the lease of a site on which he proposed to build a house and surgery, he was already practising from three surgery addresses in Birmingham. These surgeries were several miles apart and covered a wide area of the city. The agreed policy of the council and of the local medical committee is to discourage the establishment of multiple branch surgeries, as these are generally considered to be unsatisfactory from the point of view of both doctors and patients.

Dr. Prem was interviewed and readily agreed to close his most distant branch surgery, where he had very few patients. In addition, he voluntarily decided to close a second branch surgery to suit his own convenience.

(2) The Corporation had received seven applications for the vacant site and agreed to accept the council's recommendation that it should be leased to Dr. Prem. At the same time the council requested the Corporation to assist Dr. Prem by providing him with temporary accommodation pending the completion of the house and surgery.

(3) On July 17, 1948, Dr. Prem obtained the approval of the council to his resignation from the medical list, at short notice, in order that he might return to India. On July 24 Dr. Prem cancelled his resignation and decided to continue to practise in Birmingham.

(4) During the period October, 1948, to August, 1949, Dr. Prem was negotiating with the Corporation for the lease of a suitable site, as part of the original site had been acquired for other purposes.

(5) During the early part of 1950, as a result of joint discussions between the Birmingham Corporation, the executive council, and the local medical committee, it was decided that the most satisfactory method of providing accommodation for doctors on Corporation housing estates would be for the Corporation to erect houses on agreed sites and to let them to doctors nominated by the executive council, after consultation with the local medical committee.

The Corporation agreed that this arrangement should apply to the estate on which Dr. Prem was seeking accommodation, and it further agreed that the erection of this house should be treated as first priority and that the tenancy should be offered to Dr. Prem. This decision was taken a month before the council was aware of Dr. Prem's representations to a Member of Parliament and to the Minister of Health and consequently was in no way influenced by such action.

(6) Dr. Prem was informed of the arrangement on May 11, 1950, and in a written reply expressed himself as *entirely* satisfied with the proposal.

(7) During the next few months the Corporation was engaged in obtaining the approval of Government departments to the plans and in obtaining tenders for the erection of the house. On September 14, 1950, Dr. Prem was informed in writing by the Corporation that the rental of the house (architecturally designed for practice purposes and comprising waiting-room, dispensary, surgery, patients' lavatories, four bedrooms, and two reception rooms, etc.) would be £300 plus rates. Dr. Prem accepted these terms without comment in a letter dated September 16, 1950.

(8) On November 19, 1951, when the house was in course of erection, Dr. Prem wrote to the council complaining that the rent was too high. He was reminded that he had accepted the terms without comment on September 16, 1950, prior to the commencement of building, and was advised to discuss the matter with the Corporation, as the executive council had no power to intervene in tenancy agreements between the Corporation and its tenants.

In conclusion, I am to say that until May, 1950, Dr. Prem was a member of the Birmingham City Council and at the present time is a member of the Birmingham Local Medical Committee, and consequently had every possible opportunity of obtaining full information concerning the provision of doctors' houses. All the negotiations of the executive council have taken place after consultation with and the approval of the local medical committee, and have had two main objects: first, of assisting doctors to obtain proper and adequate accommodation without heavy capital outlay,

and, secondly, of providing and maintaining an efficient general medical service for the tenants of corporation housing estates. Dr. Prem's unjust criticism and incomplete statement would appear to have been occasioned by his reconsideration of the agreement he entered into with the Corporation on September 16, 1950.—I am, etc.,

Birmingham.

K. F. G. DAY,
Clerk of the Council.

Responsibility for Accommodation

SIR,—I was very interested to read Dr. D. R. Prem's letter regarding the attitude of the Birmingham Executive Council (*Supplement*, February 9, p. 55). I am in practice in the same district as Dr. Prem, coming here two years previously, in 1946. Unlike Dr. Prem, who had already had an established practice and house in Birmingham and disposed of it just previous to the commencement of the National Health Service, I was setting up practice as a principal for the first time and purchased my house and practice at Quinton. The insurance committee were very helpful indeed to me, and certainly helped me to the best of their ability whenever I needed their help or guidance. Since then I have found the executive council just as helpful and friendly and no point has been too small for them to bother about.

It has always been the rule that the doctor, not the executive council, is responsible for providing adequate accommodation for his patients. This is laid down in Regulations, First Schedule, Part 1, para. 7 (4) and (5).

As Dr. Prem says, he put up his plate a few days before July 5, 1948, having neither a house nor adequate surgery premises in the district. By doing this he was entitled under the rules of the new National Health Service to practise in the district after July 5, 1948. Surely the best thing to have done would have been to find a house and surgery first and then start practising, not start practising first and then expect the executive council to provide accommodation. There have been to my knowledge, during the past four years quite a number of modern houses for sale very close to the present surgery. These could easily have been altered to provide adequate accommodation for both a doctor and his patients. After all, four years is not long to wait for a corporation house, especially when one knows of people who have been sharing a house in this district since before the war and are still on the waiting-list for a house of their own.

The rent, at a first glance, does look high, but on reflection it may not be so. The house is quite large, and one has to remember that a doctor's house and surgery are regarded as business premises. Near the surgery is a row of corporation shops. In addition to rent, rates, and repairs the occupiers had to pay a premium to go in.—I am, etc.,

Birmingham.

E. K. MORRIS.

Plymouth's Criticism

SIR,—I am not impressed with the General Medical Services Committee's reference to the alleged "uninformed criticism" from the Plymouth Division (*Supplement*, March 1, p. 77). It has, one hopes, startled the Committee into some realization of what that nebulous quantity, the "periphery," is thinking about these prolonged discussions and the trotting to and fro between B.M.A. House and the Ministry. It is not suggested that the Plymouth Division has anything but the greatest respect and admiration for Dr. Wand's efforts; it is the results, or lack of them, that are criticized.

Dr. J. C. Arthur's suggestion that Plymouth's "profound dissatisfaction" came from "those who rarely turned up at a meeting" is very wide of the mark, because this resolution came from the Annual General Meeting of the Division, which like many other such meetings was attended by most of the Executive Committee and some two dozen others, and the "ill-informed criticism" came from those very

people who *do* read their *Journal* and *are* informed. These members are those to whom the local profession turns for information and explanation. How, then, are we supposed to answer *our* critics when we ourselves do not believe there are solid reasons for delay at Headquarters?

Miners, firemen, or any other body would have had their disputes settled long ago, and I heard Dr. D. P. Stevenson tell the Special Conference of Representatives of Local Medical Committees on July 19, 1951, that if "everything went according to plan . . . a decision should be reached by October or November" (*Supplement*, July 28, 1951, p. 32). Do we put all the blame on the General Election for this delay?

Up at Headquarters one often hears, "We do not know what the periphery think," and yet when a piece of the periphery speaks its mind the G.M.S. Committee tries to gloss over the matter as if it came from Dr. Howie Wood's "dissident members." And the same might well apply to the Committee's attitude to the proposed charge on prescriptions, a matter covered by the forthright letter from Dr. J. L. McCallum (*Supplement*, March 1, p. 82). I do not believe that all the dispensing doctors are against collecting the shilling on prescriptions. Do they show any reluctance to take a shilling for their private certificates?

If this is the best the G.M.S. Committee can do, it is hoped that the electorate will see to it that men are elected who will express the views of the *majority*. The minority had its way in 1948. Is it not high time the majority had a hearing?—I am, etc.,

Plymouth.

C. R. BARKER.

* * The Secretary of the Association states: In quoting the words reported to have been used by Dr. D. P. Stevenson at the Special Conference of Representatives of Local Medical Committees on July 19, 1951, Dr. Barker omits to quote the words, also reported: ". . . under the method of the Whitley Council and the Industrial Court. . . ." This method was subsequently superseded by the decision ratified by the Annual Conference in November that determination of the size of the central pool should be by a High Court judge.

Opening Doctors' Letters

SIR,—I was horrified to read in the national press that a patient had opened a letter given her by her doctor intended for a child psychiatrist, and, being displeased with the contents, had complained to the executive council. This council, although sympathizing with the woman's complaint that the doctor's letter said "she was not an adequate mother," decided not to proceed further with the matter, thus giving the impression that the doctor was at fault as usual.

Surely the "sympathetic" attitude adopted by this executive council to the patient for a complaint of this type gives tacit approval to the opening of confidential letters from doctor to doctor. Cannot some action be taken to prevent other doctors from enduring such injustices?—I am, etc.,

Romford, Essex.

D. D. COWEN.

Disposal of Doctors' Houses

SIR,—It will be remembered that the Conference of Local Medical Committees last November (*Supplement*, November 10, p. 197) was not satisfied with the recommendations C and D of the G.M.S. Committee which were designed to control the disposal of doctors' houses in general practice. The problem is a difficult one. There is undoubtedly a real administrative difficulty in that the approved successor to a vacancy may find, when at last he has been approved by the selection committee and the Medical Practices Committee, that the house from which the practice has always been conducted has been purchased by some other doctor. But it would be a mistake to suggest that the resulting

difficulty is of our making or that the profession itself is in any way concerned to find a remedy.

When the late Government decided in 1947 to abolish the right to buy and sell goodwill and to institute a complicated machinery for filling vacancies in general practice, it did so in spite of the warning of the profession that such a procedure would give rise to many difficulties and abuses. It persisted in its policy, and the present administrative difficulty is one of the results.

The profession has always shown the utmost willingness to co-operate with the Government in making the service run smoothly, and there seems to be a real danger that the motives for this co-operation may be misunderstood. It should be made absolutely clear that the profession has nothing to gain for itself from a solution of this particular problem, and that the only solution that it could countenance would be one depending upon positive inducement to the outgoing doctor (or his heirs) to reserve the house for the selected applicant and not upon any form of negative restriction of free disposal. It is not in accordance with the best traditions of our profession to attach opprobrious nicknames to those of our colleagues who pursue a course of action which we ourselves might not see fit to adopt, and the use in this connexion of such expressions as "piracy" would seem to be likely to confuse the issue.—I am, etc.,

Orpington, Kent.

A. C. E. BREACH.

Supplementary Ophthalmic Service

SIR,—Mr. L. M. Green's letter (*Supplement*, February 23, p. 71) makes the criticism that neither the Faculty of Ophthalmologists nor the Ophthalmic Group Committee troubles to provide a regular service of information to its members on points of general ophthalmological interest. He refers, of course, to the discussions which took place with the Ministry on the sight-testing fee.

While I cannot speak for the Faculty, I would draw Mr. Green's attention to the *Supplements* dated January 27, 1951, February 17, 1951, and February 24, 1951, in which detailed accounts were given of the negotiations we had with the Ministry, including the factors which the Minister took into account in reducing the sight-testing fee to £1. One of these factors was his obligation to make an adjustment for any underpayment to ophthalmic medical practitioners as a result of the first cut in the fee from 31s. 6d. to 25s. in anticipation of the findings of the Penman Report.

In addition I wrote personally to every ophthalmic medical practitioner on January 20, 1951, informing them of the discussion with the Ministry and of the issue involved. This included under the heading of factors to be taken under consideration the following words: "The Minister's undertaking in the letter of February 14, 1949, to make an appropriate adjustment in the fee subsequently fixed if the original was shown not to have been fully justified on the basis of remuneration then obtaining." This was followed by a letter from the Secretary of the Committee on February 15. My committee has at all times sought to keep those whom it represents fully informed on matters of major importance, and it is disturbing now to be told that no trouble is taken to keep the profession in touch with important matters of principle.

If Mr. Green cares to refer to the *Supplements* quoted above he will, I think, on reflection feel that my committee took all possible steps to inform ophthalmic medical practitioners of the negotiations we had with the Ministry on the sight-testing fee.—I am, etc.,

O. GAYER MORGAN,
Chairman, Ophthalmic Group Committee.

SIR,—Mr. L. M. Green's letter (*Supplement*, February 23, p. 71) must have been read with some astonishment by members of the ophthalmic profession. About a year ago I attended at B.M.A. House two meetings of the profession called to consider the cut in the ophthalmic examination fee, but at neither of these meetings was any statement made that the 20s. fee offered by the Minister included any sum

intended to be in respect of past liabilities. Had such an arrangement been made between our negotiators and the Minister, surely we should have been so informed. Failing this, would not my letter to which Mr. Green refers have called for some explanation by the Ophthalmic Group Committee?

It would be interesting to know whether Mr. Green's informant speaks with authority and whether the O.G.C. supports the view given. I feel that the O.G.C. owes it to the profession to give a full and unequivocal explanation of all the facts, together with some details of the mathematics involved in the calculation of the fee.

The bodies claiming to represent the ophthalmic profession have so far shown themselves to be shining examples of masterly inactivity and impotence and are rapidly leading to a feeling of defeatism among our ranks. I agree with Mr. Green that the profession would appreciate some small indication from time to time that there is still a spark of life in these bodies.—I am, etc.,

London, N.21.

S. CHAPLIN.

** The Secretary of the Association writes: The *Supplement* of January 27, 1951, included a detailed account of the negotiations which had taken place between the Ophthalmic Group Committee and the Ministry on the sight-testing fee. Under the paragraph "The Ministry Reply" clear indication was given that the Minister in proposing a fee of £1 took a number of considerations into account. One of these was his undertaking to make an appropriate adjustment in the fee subsequently fixed if the original reduction was shown not to have been fully justified on the basis of remuneration then obtaining. Further references to the negotiations were made in the *Supplement* of February 17 and February 24, 1951.

In addition, every ophthalmic medical practitioner received two letters, one from the chairman of the Ophthalmic Group Committee and one from the Secretariat, giving a detailed account of the negotiations. Although the outcome of the negotiations was far from satisfactory, every effort was made to keep ophthalmologists fully informed of what was going on.

Association Notices

AREA OF BRADFORD AND DEWSBURY DIVISIONS

Notice is hereby given that the Council of the Association has transferred the Civil Parish of Liversedge from the area of the Bradford Division to that of the Dewsbury Division.

A. MACRAE,
Secretary.

Public Health Service Members

Two members of Council are nominated and elected by members of the Association employed in the public health service as defined in By-law 1 (3). Candidates must be members of the public health service as so defined.

One Woman Member

One woman member of Council is nominated and elected by women members of the Association.

Nominations

The nominations must be on the prescribed forms, copies of which can be obtained on application to me. A notice will be published by the Council in the *British Medical Journal Supplement* on April 19, 1952, of the candidates nominated. Where contests occur, voting papers containing the names of all duly nominated candidates will be issued on April 26, 1952, from the Head Office, British Medical Association, Tavistock Square, London, W.C.1, to each member in the Group, or to the public health service

members, or to women members. A notice will be published by the Council in the *Supplement* of May 17, 1952, giving the results of the elections where there have been contests.

A. MACRAE,
Secretary.

WIGAN DIVISION.—At Prince of Wales Hotel, Southport, Wednesday, March 12, 7.30 for 8 p.m., dinner and dance.

A natural choice—for all ages.

In every case of illness, the patient's well-being is closely affected by adequate and regular bowel function. Accordingly, the selection of a suitable laxative constitutes a prime necessity in the sickroom.

'California Syrup of Figs' is outstanding in this field of therapeutics. In temporary constipation it secures easy

and effective elimination. When bowel irregularity has become chronic, 'California Syrup of Figs' may confidently be employed to restore the rhythm of intestinal function.

Exceptional palatability, simplicity of dosage and gentleness of action makes 'California Syrup of Figs' the natural choice for young and old alike.

Contains approximately 27·8% Ext. Senn. Fol. and 27·0% Syrup Ficorum (1 in 10) with carminative, sweetening, and flavouring agents.

'California Syrup of Figs' REGD.

1, WARPLE WAY, LONDON, W.3.

Lifting the veil

The distress which accompanies the menopausal years need not be allowed to go unchecked. The physician has an adequate means of relieving the several conditions which veil a woman's outlook during her middle years. The administration of SEDESTRAN is a safe and ready method of controlling these symptoms by minimal medication. Menopausal migraine and hypertension respond well to SEDESTRAN as also does dysmenorrhœa of neurogenic and psychogenic origin.

Bottles of 25 and 100 tablets. Dispensing pack — 1,000 tablets.

FOR EIGHT YEARS a number of experts have each week constituted a Brains Trust for answering questions sent to the *British Medical Journal* from all over the world.

"**ANY QUESTIONS ?**" is a current guide to the practice of medicine. Many of the authoritative answers given supply practical information not yet in the textbooks.

THE BEST of "Any Questions ?" is now offered in book form. Please reserve your copy as the edition is limited. The book is bound in cloth, fully indexed, small enough to fit the pocket, and quite indispensable to the General Practitioner in his daily work (pp. 268).

JAEGER

Jaeger body-belts are made of pure wool, for these reasons. Wool keeps its wearer cool in summer, warm in winter. Wool disposes quickly of perspiration, retaining body warmth. Wool, being porous, allows both the escape of exhalations from the skin, and the access of pure air to the skin. Jaeger body-belts sit well, stay in position, and give support without pressure. They are available in all sizes.

WRIGHT'S**COAL TAR TOILET SOAP**

This fine soap, which the medical and nursing professions find invaluable, justly merits being recommended for everyday use to those whose health is your concern. Its abundant antiseptic lather guards against infection, its pure emollients leave the skin supple and stimulated.

*A ready means
of
administering
the vitamins
A D E & K*

Cod Liver Oil is a natural carrier for the fat soluble vitamins, and with Vitamins E & K combined with the A & D in the oil, presents a ready means of overcoming the chronic shortage of natural fats containing these accessory food factors. The four vitamins are stable, Vitamin E having a protective effect against deterioration. These Capsules are of particular value in the prophylactic and curative treatment of Chilblains.

Please write for descriptive literature and samples.

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent★ testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.

Deferment of call-up for "R" practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R" practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R" practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R" practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Registrar Grades, Whole-time

(a) **REGISTRAR**: Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR**: Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years: £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER**: £350 per annum for the first post held, £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER**: Posts obtained normally not less than one year (in Scotland, two years) after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER**: Officers who have held house appointments but who are not Registrars and who have less responsibility than other hospital officers of non-consultant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement.

NORWICH, CITY AND COUNTY OF MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER
Applications are invited for the above whole-time appointment from medical practitioners possessing the appropriate qualifications and experience. The salary, calculated in accordance with Award 2285 of the Industrial Court, will be at the rate of £1,900 per annum, rising by annual increments of £50 to a maximum of £2,150 per annum, and, in addition, a car allowance will be paid. The appointment will be subject to three months' notice on either side and superannuable. The successful candidate will be required to pass a medical examination and to take up duty on or about October 21, 1952. Applications, stating age, full particulars of qualifications and experience, and accompanied by the names and addresses of three referees, should reach the undersigned not later than March 31, 1952. Bernard D. Storey, Town Clerk, City Hall, Norwich. (8989)

practitioners and the appointee in New Zealand before taking office. Junior Specialist £1,260 per annum to £1,560 per annum by annual increments of £50. Senior Specialist £1,660 per annum to £1,910 per annum by annual increments of £50. Commencing salary within these scales will be in accordance with qualifications and experience in the specialty. The amounts quoted are in New Zealand currency and are living out rates. Living accommodation is not provided. Particulars regarding payment by the Board of travelling expenses are set out in the conditions of appointment which, together with an application form, may be obtained from the Office of the High Commissioner for New Zealand, 415, Strand, London, W.C.2. Applications, addressed to the Secretary, close at the office of the Board, Kitchener Street, Auckland, New Zealand, at noon on Monday, April 7, 1952. (8487)

COLONIAL MEDICAL SERVICE

Northern Rhodesia

TWO MEDICAL OFFICERS

are required in the Health Department of Northern Rhodesia: one to work under the supervision of the Chest Physician in clinical preventive and survey work in connexion with tuberculosis, and the other for general medical work in European and African hospitals, and, in addition, to undertake the duties of Anaesthetist to Surgical Specialists. All Medical Officers are liable to undertake general duties as required by the Director of Medical Services. Appointments can be made on a permanent basis with pension (non-contributory) on retirement at the age of 55, or on short-term contract with gratuity on satisfactory completion of engagement. Doctors in the National Health Service may resign from the National Health Service but retain their superannuation rights during their time in Northern Rhodesia (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Northern Rhodesia salary on leaving Northern Rhodesia at the end of their engagement. Salary scale ranges from £865 per annum to £1,590 per annum. Starting point in the scale is determined according to age, experience, and qualifications. A temporary cost-of-living allowance at the rate of 16 per cent of basic salary is payable, subject to a maximum of £211 4s. per annum. Pension is earned at the rate of 1/600th of the final pensionable emoluments for each completed month of service. The gratuity for contract service is payable on completion of the contract at the rate of £100 to £150 per annum. Free passages in both directions are provided for officer and wife, and assisted passages for children. Annual local leave is permissible, and generous home leave is granted after each tour of three years. Quarters are provided at rental of 10 per cent of salary. Income tax at local rates. Social and recreational amenities are good. The applicant for work under the Chest Physician should preferably have had postgraduate experience in this type of work. The Anaesthetist should have had at least one year's experience in the administration of anaesthetics. Applicants for either post must possess qualifications registrable in the United Kingdom. Application forms can be obtained from the Director of Recruitment (Colonial Service), Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/153/52). (9242)

HER MAJESTY'S COLONIAL SERVICE, Malaya
Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom with one or more years' experience after qualification are required for appointment as **MEDICAL OFFICERS AND MEDICAL OFFICERS OF HEALTH**

for General Medical and Health duties

Appointment is available (a) on probation for permanent establishment; (b) on employment from the National Health Service; and (c) on short-term contract with gratuity. (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale £952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to a maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). Note. Doctors with more than one year's approved experience after age 25 (including service in Her Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g., F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of

the aggregate of their Malaya salary at the end of their engagements, under (a), including incremental increments and higher qualifications as in (a). Doctors so appointed may be offered for permanent terms at any time during their colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a), including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rate of salary and gratuity refer to doctors eligible for expatriate terms under Malayan Regulations (i.e., those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan Medical Service. The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates, which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/242/51). (5187)

HER MAJESTY'S COLONIAL SERVICE

Hong Kong

MEDICAL OFFICERS

are required for general duties in the Medical Department of Hong Kong. Appointment can be made on a permanent basis with pension (non-contributory) on retirement (the normal age of retirement is 55) or on short-term contract with gratuity on satisfactory completion of engagement. Salary scale which includes pensionable expatriation pay, ranges from £1,530 per mensem to £2,548.33 per mensem (£1,147 10s. to £1,911 5s. per annum; one dollar equals 1s. 3d.). In addition, a temporary, variable, non-pensionable cost-of-living allowance is payable according to family circumstances, and may be as much as £427 per annum for a married officer with children. Pension is earned at the rate of 1/600th of the final pensionable emoluments for each completed month of service. Officers who prefer short contract terms earn a gratuity of £37 10s. for each completed three months' service (but no pension). Quarters are provided at rental of 1/8th of basic salary (i.e., from £117 to £204 per annum, according to salary). Income tax at local rates. Free passages in both directions are provided for officer, wife and up to three children under the age of 18. Annual local leave is permissible and generous home leave is granted after each tour of four years. Climate is favourable for Europeans; a cool dry winter with well marked change of seasons. Educational facilities are available. Candidates should be under 40 years of age and possess a medical qualification registrable in the United Kingdom. They should also have had a minimum of two years' postgraduate experience. Application forms can be obtained from the Director of Recruitment (Colonial Service), Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/164/52). (9243)

Public Health—contd.**SOUTHPORT, COUNTY BOROUGH OF**

Applications are invited from registered medical practitioners (male or female) for the half-time appointment of

MEDICAL OFFICER FOR THE MENTAL HEALTH SERVICE

Salary scale £425, rising by annual increments of £25 to a maximum of £575, the commencing salary to be fixed within this grade in accordance with the qualifications and experience of the successful candidate. The person appointed will be responsible for the administration and organization of the Council's Mental Health Service under the general direction of the Medical Officer of Health, and candidates should have experience in mental illness and mental deficiency. A motor-car allowance on the "Casual Users" scale is payable, and the appointment is terminable by one month's notice. Application forms and conditions of appointment may be obtained from the Medical Officer of Health, 2, Church Street, Southport. Completed applications to be sent to the undersigned so as to arrive not later than March 22, 1952.—R. Edgar Perrins, Town Clerk, Town Hall, Southport. (8770)

**STAFFORDSHIRE COUNTY COUNCIL
ASSISTANT MEDICAL OFFICERS**

Applications are invited from fully qualified medical practitioners for the above-mentioned appointments, and those holding the Diploma of Public Health will be given preference. The candidates appointed will undertake clinical work in the School Health and Child Welfare Services under the direction of the County Medical Officer of Health, and will be required to perform such other duties as may from time to time be prescribed. The salary scale is £850 per annum rising by annual increments of £50 to a maximum of £1,150 per annum, and previous similar service may be taken into consideration when deciding the commencing rate. Each selected candidate may be required to provide a motor car, for which allowances will be paid in accordance with the County Council scale. A lodging allowance of 25s. per week, and return railway fare home every two months, will be paid for a maximum period of six months where the successful candidate is married and has to continue to maintain a home outside the geographical county while seeking housing accommodation. Each appointment will be terminable by one month's notice in writing on either side, and subject to the provisions of the appropriate Superannuation Acts and Regulations, in which connexion the selected candidates must pass a medical examination, and submit their birth certificates. Forms of application may be obtained from the undersigned, and should be returned to the County Medical Officer of Health, County Buildings, Stafford, not later than March 29, 1952, together with copies of not more than three recent testimonials.—T. H. Evans, Clerk of the County Council, County Buildings, Stafford. (9244)

SUNDERLAND EDUCATION COMMITTEE

Applications are invited from qualified medical practitioners, male or female, for full-time appointment as

ASSISTANT SCHOOL MEDICAL OFFICERS

at a salary at the rate of £850 per annum, rising by annual increments of £50 to £1,150 per annum. Preference will be given to applicants who hold a Diploma in Public Health or a Diploma in Child Health. The appointments are subject to the provisions of the Local Government Superannuation Act, 1937, and the successful candidates will be required to pass a medical examination. Application forms, to be returned not later than March 19, may be obtained from the undersigned on receipt of a stamped addressed foolscap envelope.—W. Thompson, Director of Education, Education Offices, 15, John Street, Sunderland. (8809)

**WALSALL, COUNTY BOROUGH OF
ASSISTANT MEDICAL OFFICER OF HEALTH**

Applications are invited from qualified medical practitioners for this post, and must be received not later than March 22, 1952. Preference will be given to applicants holding the D.P.H. Salary £850 by £50 to £1,150, commencing salary according to qualifications and experience. Canvassing is prohibited. Candidates must disclose relationship to any member or officer of the Council. Further particulars can be obtained from me.—W. Staley Brookes, Town Clerk, The Council House, Walsall. (8869)

ADMINISTRATIVE**SOUTH-WESTERN REGIONAL HOSPITAL
BOARD**

Applications are invited from registered medical practitioners for the post of

**ASSISTANT SENIOR MEDICAL OFFICER
(Whole-time)**

on the headquarters staff of the Board's office. The salary is £1,450 by £50 to £1,650, subject to review by the Medical (Whitley) Council for the Health Services. The successful candidate will be engaged on general administrative duties under the Board's Senior Administrative Medical Officer. Experience of public health and hospital administration would be an advantage. The appointment is subject to the provisions of the National Health

Service (Superannuation) Regulations. The conditions of service approved by the Department of Health. Applications, stating age, qualifications, and experience, and giving the names of three referees, should reach the Secretary of the Board at 5, Cotham Lawn Road, Bristol, not later than March 28, 1952. (9147)

COMMERCIAL APPOINTMENTS

Full particulars may be obtained from the Secretary:
The Convalescent Home is HOVE VILLA, BRIGHTON.

A combination of qualities

The claims of 'Dettol' do not rest on any single quality desirable in an antiseptic, but rather upon the combination of several essential properties. It can be used at fully effective strengths with safety; without risk of poisoning, discomfort or damage to tissue. It retains a high bactericidal potency in the presence of blood; it is stable, and agreeable in use.

'DETTOL' **THE MODERN ANTISEPTIC**

'Dettol' is available in 2 gallon and 5 gallon tins free of Purchase Tax *for dispensing purposes only*. Smaller sizes, including 1 gallon tins for public use are subject to Purchase Tax.

Introducing a new Contraceptive Cream

ANTEMIN has been formulated in the light of modern research to afford all the qualities desirable in a contraceptive preparation.

Antemin

Formula:

Sodium dioctyl sulpho succinate	0.25%
Ricinoleic acid	1.00%
Boric acid	1.00%
Trioxymethylene	0.15%

Manufactured by

COATES & COOPER LTD.

PYRAMID WORKS · WEST DRAYTON · MIDDX.

- Cosmetic type cream base—Non-friable and tenacious.
- Spermicidal activity S/8.
- pH. value approximating to normal vaginal secretion.
- Non-irritant to the vaginal mucosa—Non-toxic.
- Simple in application. Inexpensive.
- Approved by the Family Planning Association for use in conjunction with a mechanical barrier.

Literature and clinical sample available on request.

FIRST ANNUAL REPORT ON STRESS

SUPPLEMENT TO
THE MONOGRAPH
"STRESS"

by **HANS SELYE**
M.D., Ph.D. (Prague)
D.Sc. (McGill), F.R.S.(C.)

HIGHLIGHTS OF THE BOOK.

- ★ It deals with current developments in the field of ACTH, Cortisone, STH, and the adaptation syndrome in general.
- ★ It presents a new unified theory of medicine.
- ★ It acts as a guide to the entire literature on Stress.
- ★ It combines an extensive classified index of pertinent facts on the Stress problem and a concise textbook-like evaluation of the principal findings.
- ★ It marks the start of an annual series of such reports which will embody the latest developments with ACTH, Cortisone, and STH.

NEW BOOKS AND EDITIONS

6½ × 10 in. Sixth Edition. In 5 parts. Approx 1,000 pp. Illustrated in colour. Price per Part, 21s., postage 5d. Part IV—Now ready. Part V—Ready probably September

EMERGENCY SURGERY

By HAMILTON BAILEY, Assisted by N. M. MATHESON
The work has been completely revised, and many new illustrations have been added and a large number of others re-made. The format has been altered and the type entirely re-set. A cloth case for binding the volume will be supplied with Part V.

5½ × 8½ in. 336 pp. 20 plates. 21s., post 7d.

THE ENGLISH PIONEERS OF ANÆSTHESIA (Beddoes, Davy, and Hickman)

By F. F. CARTWRIGHT
Short biographies in which the author has given proper credit, first of all, to the work of Beddoes and Davy in the development of anæsthesia and then to Hickman, whose work forms a logical sequence.

Second Edition. 6½ × 9½ in. In 4 volumes. Vols. I, II, and III each 52s. 6d., post 11d. Vol. IV, 560 pp. 237 illustrations. 63s., post 1s. 1d.

MALIGNANT DISEASE AND ITS TREATMENT BY RADIUM

By SIR STANFORD CADE, K.B.E., C.B.
The book sets out to help the radiotherapist in his task, to assist the surgeon in the selection of the method of treatment, and to provide the doctor with an account of the clinical and pathological aspects of malignant disease.

7 × 10½ in. 304 pp. 24 plates, many in colour. 60s., post 11d.

NEW OUTLOOK ON MENTAL DISEASES

By F. A. PICKWORTH
The correlation between mental disease and bodily disorder, and the significance of the pathology usually found in disturbances of the mind, form the basis of this new and original monograph.

4½ × 7½ in. 525 pp. 84 illustrations. 30s., post 6d.

A SYNOPSIS OF NEUROLOGY

By W. F. TISSINGTON TATLOW, J. A. ARDIS, and J. A. R. BICKFORD

While not claiming to take the place of the large treatises on neurology, it covers in compact form the whole of the specialty with the exception of neurological surgery.

JOHN WRIGHT & SONS: BRISTOL,

in the spring—

the debility which is an inevitable legacy of a winter characterised by epidemics of influenza and measles requires an efficient tonic as an essential first step towards recovery. Here is a tonic containing glycerophosphates iron, manganese, caffeine citrate, tincture of nux vomica and vitamin B₁ in a palatable and easily assimilated form:

the tonic—

COLLOTONE

Each fl. oz. (28 ml.) contains	{	Iron B.P. as organic complexes	47 mgs. (0.165%)	Sodium glycerophosphate B.P.C.	207 mgs. (0.73%)
		Iron and manganese citrate B.P.C.	85 mgs. (0.3%)	Vitamin B ₁ B.P.	2.67 mgs. (0.0094%)
		Calcium glycerophosphate B.P.C.	248 mgs. (0.875%)	Tincture of nux vomica B.P.	0.3 ml. (1.1%)
		Potassium glycerophosphate B.P.C.	224 mgs. (0.79%)	Caffeine citrate B.P.C.	170 mgs. (0.6%)

Aurally Speaking

In the measurement of hearing loss, the Pure Tone Audiometer TF 895 conforms to the specification of the Committee on Electro-Acoustics appointed by the Medical Research Council. Each instrument, with its high-fidelity head set, is standardised against N.P.L. determinations and provides sinusoidal tones between 125 and 8000 cycles per second. The patient, who may be instructed orally through a crystal microphone, responds to acuity tests via the signal lamp on the instrument panel. Please ask for further information of this improved aid to audiometry.

VERILOID

Product of Riker Research

Trade
Mark

A potent alkaloidal fraction of Veratrum viride — biologically standardised for hypotensive activity in mammals — a new active principle not heretofore available, for the treatment of hypertension.

An entirely new drug, Veriloid presents only the hypotensive ester alkaloids of Veratrum viride freed from the irritant and inert dross of the crude root. This active principle, because it is biologically standardised, is absolutely uniform in its pharmacological action.

Individualisation of dosage is essential for maximum therapeutic benefit. In the majority of patients the average daily requirement of 9 to 15 mg. given in divided dosage three times daily leads to a clinically significant drop in arterial tension brought about by relaxation of the smaller arterioles. This effect is readily maintained for as long as the drug is given, for tolerance to Veriloid usually does not develop. Concomitantly, gratifying subjective improvement is discernible by the patient.

Veriloid has been found effective in malignant hypertension, severe essential hypertension and in moderate elevation of the blood pressure. It is available on prescription through all pharmacies in slow dissolving tablets containing 1.0 mg., in bottles of 100 and 500. Veriloid may be prescribed on Form E.C.10 without restriction.

THE Original Germicidal Soap containing HEXACHLOROPHENE

Tests show 95% reduction of Bacterial Flora compared
with 15% reduction with ordinary soap

Cultural tests carried out in the United States showed a 95% reduction of bacterial flora as compared with 15% reduction with ordinary toilet soaps. Authors have stated that the remarkably lowered resident flora following the use of a soap containing Hexachlorophene has

not resulted from bacteriostasis but from actual killing. There is, too, a cumulative factor in Hexachlorophene which is important in maintaining low skin bacterial flora. In these investigations it was found that the maximum reduction

A large hospital in Britain reports:—"The incidence of septic skin conditions is increasing at the hospitals which we are using as a 'control' but it has not increased at the hospital where we are using DERL".

of bacterial flora was achieved after a period of 5 to 7 days, and did not return to normal for another 7 days after ceasing to use the soap. It follows, therefore, that the regular use of "Derl" will exert a continuous bacteriostatic effect between ablutions. No

cases of sensitization have been reported. Members of the medical profession are showing a keen interest in "Derl", the first all-British soap to contain Hexachlorophene. Samples will be gladly sent on request.

Derl

THE SOAP WITH THE MOST EFFECTIVE
BACTERIOCIDAL ACTION

Available from Chemists only

A PRODUCT OF ROBERTS WINDSOR SOAP COMPANY LIMITED, GLADSTONE WORKS, WINDSOR

In Para-nasal infections **ARGYROL** provides
physiological action
without CNS stimulation
or rebound congestion

● A return to normal function by the decongestive, demulcent and bacteriostatic actions of ARGYROL is achieved without the side effects and rebound so frequent with many vasoconstrictors. In the solution of para-nasal problems, the ultimate advantages of using ARGYROL are readily apparent.

The ARGYROL Technique

1. The nasal meatus . . . by 20 per cent ARGYROL instillations through the nasolacrimal duct.
2. The nasal passages . . . with 10 per cent ARGYROL solution in drops.
3. The nasal cavities . . . with 10 per cent ARGYROL by nasal tamponage.

Its Three-fold Effect

1. Decongests without irritation to the membrane and without ciliary injury.
2. Definitely bacteriostatic, yet non-toxic to tissue.
3. Stimulates secretion and cleanses, thereby enhancing Nature's own first line of defence.

Decongestion and Relief without Rebound ● Decongestion without Dysfunction
 — the medication of choice in treating para-nasal infection

COMPOSITION :

ARGYROL is a colloidal preparation containing 20% silver combined with alkali-treated protein to give solutions with a silver ion concentration near 10-8 m, a pH near 9, and a particle diameter between 1-10th and 1-100th that of *Staphylococcus aureus*.

*Argyrol is a registered trade mark, the property of the makers A. C. BARNES CO. NEW BRUNSWICK, N.J.

STRAINS & SPRAINS

A new approach to Vaso-Dilatation

*New powerful penetrative agent ensures
 subcutaneous penetration of histamine*

It has long been recognised that histamine, in dilating the capillaries, acts as a pain-reliever. In 'Algipan' the difficulty hitherto experienced in applying the drug to the subcutaneous layers without injection has now been overcome. The potent penetrative agent methyl nicotinate enables surface applications of histamine to reach the deeper tissues, where it promotes an increased flow of blood and relieves pain. A comforting rubefacient action is exerted by the glycol salicylate and capsicin.

The penetrative, warming and pain-relieving properties of 'Algipan' bring rapid relief. 'Algipan' is a pleasant non-greasy, water-soluble cream, and only a very gentle rubbing is needed.

'Algipan'

•Trade Mark.

FORMULA :—Methyl Nicotinate 1.0%, Histamine Dihydrochloride 0.1%,
 Glycol Salicylate 10.0%, Capsicin 0.1%.

ANTIRHEUMATIC EFFECTS OF HYDROCORTISONE (FREE ALCOHOL), HYDROCORTISONE ACETATE, AND CORTISONE (FREE ALCOHOL) AS COMPARED WITH CORTISONE ACETATE

RESULTS FROM ORAL ADMINISTRATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

BY

EDWARD W. BOLAND, M.D., M.S.Med., F.A.C.P.

Los Angeles, California

The results of prolonged uninterrupted cortisone acetate therapy given orally to patients with rheumatoid arthritis were recently reported.¹ By using initial suppressive amounts of the hormone, then gradually reducing the dosage in step-like manner, and finally employing smaller maintenance doses, it was possible to sustain satisfactory, though not complete, rheumatic control in approximately two-thirds of the patients. Adequate degrees of improvement were maintained in 47% of severe cases, in 70% of moderately severe cases, and in 92% of moderate and mild cases. Results were poorer in those patients whose disease was severe, because they required continued large or relatively large maintenance amounts of the hormone which often could not be tolerated, as they incited objectionable hormonal complications; large but efficient doses frequently had to be reduced, with sacrifice to clinical improvement.

The limitations of cortisone acetate as a therapeutic agent, together with its cost, and, until recently, its restricted supply, have led investigators to search for steroidal substitutes which might possess similar anti-inflammatory and anti-allergic properties. Many substances, some closely allied chemically to cortisone, have been tested by critical observers and have been found devoid of significant antirheumatic activity in the dosage ranges explored. Among these may be listed: substance S of Reichstein (11-desoxycorticosterone),^{2,3} compound A of Kendall (11-dehydrocorticosterone),^{4,6} 21-desoxycortisone,⁵ 21-desoxy-11-dehydrocorticosterone,⁵ desoxycorticosterone acetate (alone or with ascorbic acid),^{6,7,8,9,10} 17-hydroxyprogesterone,^{11,12} pregnenethiolone acetate,^{3,7} delta-5-pregnenolone,^{5,12,13} and 21-acetoxypregnenolone.^{2,5,12} An exception has been Kendall's compound F (17-hydroxycorticosterone: "substance M" of Reichstein), recently named "hydrocortisone," which has shown physiological activity at least comparable to that of cortisone. Weak antirheumatic action has been demonstrated also by certain adrenal cortical extracts, their strength apparently depending upon the amounts of cortisone or hydrocortisone they contain.⁵

In April, 1951, small quantities of hydrocortisone acetate were made available to us, and two patients with rheumatoid arthritis were given the drug orally. The doses needed to suppress the rheumatic manifestations

were substantially greater than those ordinarily required for cortisone acetate.¹⁴ Conversely, pilot trials made later with hydrocortisone (free alcohol) indicated that this substance was highly effective and perhaps even more potent than cortisone acetate. Subsequently, when supplies of materials permitted, a systematic study designed to compare the antirheumatic potencies of cortisone acetate, hydrocortisone (free alcohol), hydrocortisone acetate, and cortisone (free alcohol) was undertaken. Appraisals of the relative clinical effectiveness of these compounds were made by: (1) estimating differences in initial clinical response to large suppressive doses, and (2) comparing the maintenance doses required to uphold equivalent degrees of clinical improvement in the same patient. The results of this investigation are reported here.

In comparing the maintenance-dosage requirements of other compounds with those already established for cortisone acetate, care was taken to select only those patients whose maintenance doses of cortisone acetate had remained quite stable over periods of weeks or months. Transfers from one substance to another were not made in rapid sequence and patients were usually kept on the test preparation for at least two or three weeks. They were then transferred back to the original compound in order to cross-check differences. During the study attempts were made to compare the amounts of the compounds needed to sustain marked (70 to 85%) improvement, but not complete suppression of the disease. Thus sufficient subjective and objective manifestations remained to allow changes in rheumatic response to be measured.

Cortisone Acetate

The favourable influence of cortisone acetate therapy on rheumatoid arthritis has been repeatedly documented. In more than 150 patients treated with the compound by oral administration we have followed a fairly uniform plan of dosage, which has consisted of three stages: (1) a period of initial suppressive doses; (2) a period of gradual dose reduction; and (3) a period of smaller maintenance-dose administration.^{1,15,16,17}

Initial suppressive therapy usually has been given as follows: for severe and moderately severe cases, 200 or 150 mg. for the first one or two days, followed by 100 mg.

daily; for moderate and mild cases, 100 mg. on the first and subsequent days. The drug has been prescribed in four divided doses daily, at meal-times and at bedtime. Amounts of 100 mg. have been continued until the clinical manifestations were suppressed satisfactorily; the number of days required for this has varied, more or less, with the initial activity of the disease, averaging, for example, about 21 days for severe cases and about 14 days for moderate cases. The dosage then has been gradually reduced in steplike fashion, by 12.5 mg. (half a tablet) at a time at intervals of every five to seven days. The smallest daily amount which would sustain adequate suppression of rheumatic symptoms, not necessarily full symptomatic relief, has been regarded as the patient's maintenance dose. This dose has been continued uninterruptedly, adjustments being made from time to time to counteract fluctuations in disease activity.

With large suppressive amounts of cortisone acetate given by mouth, symptoms generally begin to subside within the first 24 hours of treatment, and almost invariably some response is noted within the first 48 hours. Early benefits consist in reduction of aching and stiffness, lessening of articular tenderness and pain, increase in range of joint motion, lessening of fatigue, and increased appetite. Joint swelling and other reversible objective changes recede more gradually, but with continued administration the overall improvement progresses. Elevated erythrocyte sedimentation rates are corrected more slowly than are the joint manifestations, and their reductions usually lag several days behind clinical improvement. In spite of continued large daily doses of the hormone, however, sedimentation rates may at times fail to decrease to levels commensurate with the rheumatic response.

After the manifestations have been brought under initial control and the dose has been gradually reduced, the daily amount of cortisone acetate needed to maintain satisfactory symptomatic suppression varies, but it depends to a large extent on the initial activity of the rheumatoid arthritis—the more severe the disease, the more cortisone acetate required. Usual ranges for maintenance doses have been: 62.5 to 125 mg. a day for severe cases; 50 to 75 mg. a day for moderately severe cases; 37.5 to 62.5 mg. for moderate cases; and 25 to 50 mg. a day for mild cases. In nearly two-thirds of patients the dosage has remained fairly constant for months, with only minor adjustments being needed periodically. In about one-third of patients the amounts of hormone required have fluctuated considerably from time to time, and major manipulations of dosage have been necessary to offset changes in disease activity.

Hydrocortisone (Free Alcohol)

Hydrocortisone (Kendall's compound F, free alcohol: 17-hydroxycorticosterone) differs from cortisone (Kendall's compound E, free alcohol: 17-hydroxy-11-dehydrocorticosterone) in that a hydroxy radical instead of a ketone group is present at the eleventh carbon position of the steroid nucleus. From facts now available it seems probable that hydrocortisone rather than cortisone is the chief glyco-genically active corticoid secreted by the adrenal gland, at least under conditions of stress.^{18,19} A number of laboratory procedures indicate that hydrocortisone is more active physiologically than cortisone. Comparisons made from muscle-work tests, assays of liver glycogen, and ability to incite regressive changes in the thymus and adrenals have shown that when the non-esterified forms of the two hormones are given intravenously or subcutaneously hydrocortisone is approximately twice as potent as cortisone.^{20-21,22,23} It also appears that one-half as much hydrocortisone as cortisone will promote an equivalent eosinopenic response.²⁴

Meagre quantities of hydrocortisone (free alcohol) have been available for laboratory and clinical research because production of the hormone has depended upon complicated processes of biosynthesis. These have involved the trans-formation of 11-desoxy-17-hydrocorticosterone (Reichstein's

compound S)—a steroid which may be derived from soy beans and which is devoid of anti-inflammatory activity—to hydrocortisone through the action of adrenal cortical enzymes. By enriching the substrate with 11-desoxy-17-hydrocorticosterone and perfusing it through intact isolated bovine adrenal glands or by adding it to and incubating it with slices of adrenal cortex, this steroid is converted (by placing a hydroxy radical at the eleventh carbon atom) to hydrocortisone. Very recently small amounts of the hormone produced by partial chemical synthesis have been made available for trial.

In 1949 Hench and colleagues demonstrated that hydrocortisone (free alcohol), like cortisone and corticotropin (A.C.T.H.), possessed antirheumatic activity when administered systemically.^{25,26,27} They gave a total of 900 mg. of the hormone intramuscularly to one patient with rheumatoid arthritis over a 12-day period and noted that the articular manifestations subsided rapidly; overall relief was estimated as 60% and the erythrocyte sedimentation rate was reduced from 85 to 24 mm. in one hour. No other accounts of the effects of hydrocortisone (free alcohol) given systemically to patients with rheumatoid arthritis have been recorded.

Experience with Suppressive Doses of Hydrocortisone (Free Alcohol) Given Orally

Five patients with rheumatoid arthritis of the peripheral type who had not previously received hormonal therapy for arthritis were given large initial doses of hydrocortisone (free alcohol) by mouth.* The disease was graded as severe in one patient, moderately severe in three, and moderate in one; erythrocyte sedimentation rates before treatment were 119, 61, 60, 53, and 48 mm. in one hour (Westergren method) in the respective patients. Four of the subjects were women and one was a man. Their ages ranged from 42 to 56 years.

The one patient with severe disease received 150 mg. of the hormone daily for two days and then 100 mg. each day for 13 days. The three patients with moderately severe and the one patient with moderate rheumatoid arthritis received 100 mg. on the first day and for several days thereafter. Because supplies of hydrocortisone were limited, the doses given on the first day of treatment were smaller than those customarily employed for cortisone acetate in cases of similar severity.

The results from suppressive doses of hydrocortisone (free alcohol) will be reported elsewhere in greater detail.²⁷ The initial response was strikingly prompt in each patient, and symptoms such as aching and stiffness began to subside within three, four, six, seven, and ten hours respectively after the first dose of the hormone. In four patients (three with moderately severe and one with moderate rheumatoid arthritis) subsequent progress was extremely rapid, and very marked degrees of overall improvement (more than 85%), as gauged by both objective and subjective criteria, resulted after four, six, six, and eight days. In these the improvement progressed at a more rapid rate and was more complete than that which usually follows oral cortisone acetate therapy within such periods, even when larger doses are given on the first day. The fifth patient (with severe disease) responded less dramatically, and the improvement was graded as marked after 15 days; the rate of improvement was considered to be about the same as might have resulted from cortisone acetate given in identical doses.

Erythrocyte sedimentation rates were lowered with remarkable speed and, in contrast to the lag which is often noted during cortisone acetate therapy, reductions kept pace closely behind clinical improvement. Elevated rates in the five patients were reduced as follows: 53 to 10 mm. in 7 days, 60 to 20 mm. in 7 days, 61 to 11 mm. in 10 days, 48 to 16 mm. in 6 days, and 119 to 39 mm. in 15 days.

*Gratitude is expressed to G. D. Searle & Co., who supplied most of the hydrocortisone (free alcohol); to Merck & Co., Inc., who supplied the cortisone acetate; and to the Upjohn Company, who supplied part of the hydrocortisone (free alcohol).

Comparisons of Maintenance-dosage Requirements of Cortisone Acetate and Hydrocortisone (Free Alcohol)

By directly comparing the maintenance doses required in the same patient to provide similar antirheumatic control, appraisals of the relative potencies of cortisone acetate and hydrocortisone (free alcohol) could be made more accurately than by estimating differences in the immediate response to suppressive doses. Ten patients with rheumatoid arthritis who had been treated uninterruptedly with cortisone acetate orally for long periods (3 to 16 months), and whose maintenance requirements were stable and well established, were transferred directly to hydrocortisone (free alcohol). Uniformly the patients needed smaller amounts of hydrocortisone (free alcohol) for equivalent degrees of clinical improvement. Dosage differences were clearly defined and, milligram for milligram, hydrocortisone (free alcohol) was found to be approximately 50% more potent than cortisone acetate. Dosage ratios of cortisone acetate to hydrocortisone (free alcohol) ranged from 1.43:1 to 1.7:1 among the ten patients, and the average ratio for the group was 1.56:1 (Table I).

In three of the five patients the initial response was definitely less than would ordinarily be experienced with corresponding large suppressive doses of cortisone acetate, but in two patients (both with moderately severe disease) the progress of improvement was similar. In the five patients some degree of symptomatic relief was noted within 8, 15, 24, 24, and 30 hours after the first dose of hydrocortisone acetate, but in three of them the immediate reaction was not striking, and at the end of several days of treatment the overall improvement was considered to be distinctly less than should have resulted from similar amounts of cortisone acetate.

Response to suppressive therapy varied among the five patients as follows. The first patient, with moderately severe rheumatoid arthritis, exhibited moderate symptomatic relief after the first day's treatment with 200 mg. of hydrocortisone acetate, and after 48 hours some improvement in the objective joint findings was recorded. Two days after the dose was reduced to 100 mg. a day, however, regression ensued and very little additional improvement resulted from continued administration. After 15 days, improvement was

Hydrocortisone Acetate

Hydrocortisone acetate (17-hydroxycorticosterone-21-acetate: compound F acetate) is produced by partial chemical synthesis from desoxycholic acid, through a similar but more complex process than that used in the manufacture of cortisone acetate. Reports of systemic administration of this compound to patients with rheumatoid arthritis have been few. Perera and associates²⁸ gave the drug intramuscularly to two patients with the disease; one received 100 mg. a day for 24 days and the other 12.5 mg. a day for 11 days. They concluded that the clinical and metabolic effects may have been somewhat less than would have occurred with cortisone acetate. Ward and co-workers²⁹ judged that the improvement which resulted in two patients who received the compound orally was comparable to that expected from cortisone acetate in corresponding doses.

Experience with Suppressive Doses of Hydrocortisone Acetate*

The acetate ester of hydrocortisone was administered orally as initial treatment to five women, one with severe and four with moderately severe rheumatoid arthritis. Erythrocyte sedimentation rates before treatment were recorded as 103, 67, 58, 53, and 50 mm. in one hour (Westergren method). Dosages used were identical to those customarily employed with cortisone acetate in cases of like severity: 200 mg. in divided doses was given on the first and second days of treatment and 100 mg. daily thereafter to the patient with severe arthritis; 200 mg. was administered on the first day and 100 mg. on subsequent days to the four patients with moderately severe disease.

*The hydrocortisone acetate used in this investigation was supplied by Merck & Co., Inc.

graded as slight (less than 30%) and the erythrocyte sedimentation rate had not changed significantly (58 to 56 mm. in one hour). The dose of hydrocortisone acetate was then raised to 200 mg. a day for 10 days; further suppression of the disease manifestations promptly ensued, but endocrine side-reactions, consisting of pronounced mooning of the face, nervousness, insomnia, and oedema of the lower legs, also developed.

The second patient suffered from severe rheumatoid arthritis, and previously, for a period of 11 months, she had responded well to uninterrupted cortisone acetate administration. The immediate improvement from cortisone acetate had been dramatic, and satisfactory control was held with daily amounts ranging from 50 to 75 mg. Cortisone acetate therapy had been discontinued five months beforehand in order to ascertain the rate of return of adrenal cortical function following long-term therapy; functional recovery, as indicated by the eosinopenic response to corticotropin and urinary 17-ketosteroid determinations, had returned to normal within 45 days after withdrawal. The improvement resulting from hydrocortisone acetate in amounts of 200 mg. daily for two days and then 100 mg. a day was graded as slight. After 19 days of treatment overall improvement was estimated as between 20 and 30% and the sedimentation rate had not decreased greatly, from 103 to 87 mm. in one hour. The preparation was then given in amounts of 150 mg. a day for a period of nine days; this afforded somewhat greater relief, and improvement was finally graded as moderate (about 50%). At this point transfer to cortisone acetate in amounts of 100 mg. a day was accomplished. Within 18 hours there was striking acceleration of improvement, and continued administration resulted in rapid sup-

TABLE II.—Maintenance Requirements for Cortisone Acetate and Hydrocortisone Acetate Given Orally in Rheumatoid Arthritis

pression of the rheumatic manifestations, comparable to that which had been experienced from previous treatment with cortisone acetate.

The third patient, with moderately severe disease, experienced rapid and progressive improvement from suppressive doses of hydrocortisone acetate, which at the end of 16 days was graded as marked (80%). Thereafter the dosage was gradually reduced to a maintenance level of 62.5 mg. a day, which was sufficient to uphold satisfactory suppression of the clinical manifestations. The erythrocyte sedimentation rate failed to reflect the good rheumatic response, however, and at the end of 22 days of treatment had decreased only from 67 to 46 mm. in one hour. Transfer to cortisone acetate was subsequently made, and the same maintenance dose was required to provide equivalent clinical control.

The fourth patient, with moderately severe rheumatoid arthritis, responded slowly and undramatically to initial suppressive doses of hydrocortisone acetate, and after 20 days of treatment the overall improvement was graded as moderate or about 50%. The erythrocyte sedimentation rate decreased during the period from 53 to 40 mm. in one hour.

The fifth patient, with moderately severe disease, responded well to 200 mg. of hydrocortisone acetate on the first day, noting subjective improvement within 24 hours after the initial divided dose. Subsequent progress on total daily amounts of 100 mg. was steady, and after 19 days of treatment the improvement was graded as marked (about 80%). The erythrocyte sedimentation rate during this period was reduced from 50 to 20 mm. in one hour.

Comparisons of Maintenance-dosage Requirements of Cortisone Acetate and Hydrocortisone Acetate

In contrast to hydrocortisone (free alcohol), which was found to be more potent than cortisone acetate when the maintenance requirements of the two substances were tested on the same patients, hydrocortisone acetate was less effective, milligram for milligram, than cortisone acetate in eight of nine patients studied. Dosage ratios of cortisone acetate to hydrocortisone acetate ranged from 1:1 to 1.64:1 among the nine patients, with an average for the group of 1.37:1 (Table II).

Comparisons of Maintenance-dosage Requirements of Hydrocortisone (Free Alcohol) and Hydrocortisone Acetate

Direct comparisons of these two compounds in the same patients clearly demonstrated that hydrocortisone (free alcohol) was distinctly superior to hydrocortisone acetate in controlling the manifestations of rheumatoid arthritis. Results were fairly uniform in nine patients tested, and indicated that hydrocortisone (free alcohol) was nearly twice as potent, milligram for milligram, when the two substances were given by mouth (Table III).

Cortisone (Free Alcohol)

Of the 21 rheumatoid arthritis patients with whom Hench, Kendall, Slocumb, and Polley^{25, 26} originally demonstrated that cortisone exerted an inhibiting influence on the disease, 9 received the free hormone and 12 were given the acetate ester as initial treatment. The relative therapeutic potencies of the two preparations were not compared directly by them.

When our studies revealed that hydrocortisone (free alcohol) was distinctly superior in antirheumatic activity to hydrocortisone acetate when they were administered orally, the question arose whether a similar discrepancy might exist between the free and acetated forms of cortisone. Cortisone (free alcohol)* was made available to us in small quantities, and maintenance-dosage requirements for the hormone were compared with those for cortisone acetate in seven patients, and with those for hydrocortisone (free alcohol) in six patients. The data evolved from these comparisons are given in Table IV. Supplies were not sufficient to test the effects of initial suppressive doses in previously untreated patients.

Cortisone (free alcohol) and cortisone acetate were found to be approximately equal in their antirheumatic potencies when administered by mouth. Except for minor variations in three of the seven patients, the maintenance dosages required for the two compounds were interchangeable.

Hydrocortisone (free alcohol) proved to be more effective, milligram for milligram, than cortisone (free alcohol). Although dosage differences among the individual patients showed less uniformity, the average calculated dosage ratio was much the same as with cortisone acetate. The dosage ratio of cortisone (free alcohol) to hydrocortisone (free alcohol) ranged in the six patients from 1.25:1 to 2.08:1, with an average ratio for the group of 1.6:1—against 1.56:1 for cortisone acetate to hydrocortisone (free alcohol).

*The cortisone (free alcohol) used in this investigation, produced by partial chemical synthesis, was supplied by the Upjohn Company.

Comment

Data derived from the present study indicate that when administered orally hydrocortisone (free alcohol) is, milligram for milligram, approximately 50% more potent than either cortisone acetate or cortisone (free alcohol), and nearly twice as effective as hydrocortisone acetate. These observations suggest that hydrocortisone (free alcohol) may prove to be superior to cortisone acetate as a therapeutic agent. Although the hormone used in the present study was produced by expensive and complicated procedures of biosynthesis, it has been made recently by partial chemical synthesis from a precursor of cortisone. If future investigations prove that the hormone has distinct therapeutic advantages, it is probable that practical methods for its commercial manufacture will be found.

The number of cases studied were too few and the periods of observation were too short to allow the incidence of the adverse hormonal effects from hydrocortisone (free alcohol), hydrocortisone acetate, or cortisone (free alcohol) to be compared with those already known for cortisone acetate. However, it seems that the greater antirheumatic activity of hydrocortisone (free alcohol) is not accompanied by a correspondingly greater tendency to produce adverse reactions. Endocrine complications were present in several patients during the administration of maintenance doses of cortisone acetate, and these disappeared or diminished when the patients were transferred to smaller but equally effective amounts of hydrocortisone (free alcohol). Five of the ten patients transferred from cortisone acetate to hydrocortisone (free alcohol) had signs of hormonal excess prior to transfer. Slight to moderate oedema, which was present beforehand in four patients, disappeared entirely after hydrocortisone (free alcohol) therapy was instituted. Facial mooning, which was present in two patients, became less noticeable in one and receded completely in the other. In no patient did new hormonal complications develop after transfer to hydrocortisone (free alcohol). We believe that this lessening of adverse effects may be accounted for by the fact that smaller doses of hydrocortisone (free alcohol) were employed to control the rheumatoid arthritis.

The reasons for the marked disparity in therapeutic effectiveness between hydrocortisone (free alcohol) and hydrocortisone acetate when administered orally are not entirely clear, but the relatively low solubility of hydrocortisone acetate may provide at least part of the explanation. Recent studies made at the Merck Laboratories have demonstrated that hydrocortisone (free alcohol), when compared with hydrocortisone acetate, is ap-

proximately 28 times more soluble in water, six times more soluble in synovial fluid, 35 times more soluble in plasma, and 36 times more soluble in serum albumin.³⁰ The lower solubility of hydrocortisone acetate could substantially lessen the rate and degree of its alimentary absorption.

Recently Hollander and co-workers,^{31 32} and others^{33 34} have observed that intra-articular injections of small quantities (25 to 50 mg.) of hydrocortisone acetate are highly effective in temporarily suppressing the inflammatory reaction in individual joints treated, but that similar injections of cortisone acetate are not so successful. These findings are in contrast to our results from oral administration, in which cortisone acetate exhibited the greater potency. Again this could be explained, but possibly only in part, on the basis of differences in solubility and absorption of the two compounds. Solubility data have revealed that cortisone acetate is approximately twice as soluble in water as hydrocortisone acetate, nine times as soluble in synovial fluid, eight times as soluble in plasma, and 18 times as soluble in serum albumin.³⁰ Whereas the low solubility of hydrocortisone acetate may lessen its therapeutic effectiveness with oral administration, it may, by delaying absorption from the joint and allowing more prolonged local action, serve as an advantage with intra-articular application.

Summary

Comparisons of the antirheumatic effects of hydrocortisone (free alcohol), hydrocortisone acetate, cortisone (free alcohol), and cortisone acetate given orally for short periods were made in patients with rheumatoid arthritis. The relative potencies of the preparations were appraised by estimating the differences in clinical response to initial suppressive doses, and by comparing directly in the same patient the maintenance doses required to uphold similar degrees of clinical improvement.

Hydrocortisone (free alcohol) was found to possess greater antirheumatic activity, milligram for milligram, than any of the other three preparations when given by mouth. This substance, administered in large initial doses, was highly efficient in suppressing the disease manifestations of rheumatoid arthritis, and its action appeared to be more rapid than that regularly encountered with cortisone acetate. By comparing the maintenance doses required for equivalent clinical control, hydrocortisone (free alcohol) was found to be approximately 50% more potent than either cortisone (free alcohol) or cortisone acetate, and nearly twice as effective as hydrocortisone acetate.

In a small number of patients tested by comparing maintenance-dosage requirements the effectiveness of cortisone (free alcohol) and cortisone acetate appeared to be about equal.

The relative incidence of endocrine complications from the various preparations could not be determined from the short-term studies involved. However, the greater antirheumatic activity of hydrocortisone (free alcohol) did not seem to be accompanied by a correspondingly greater tendency to produce adverse physiological effects. In several patients signs of hormonal excess present while on maintenance doses of cortisone acetate actually diminished or disappeared after transfers were made to smaller, but equally effective, doses of hydrocortisone (free alcohol).

The marked disparity in therapeutic effectiveness between hydrocortisone (free alcohol) and hydrocortisone acetate when given by mouth may be accounted for, at least in part, by differences in solubility of the compounds. The low solubility of hydrocortisone acetate may substantially lessen its alimentary absorption.

According to a report from the Informacion Medica Española the Spanish Government has allotted money for the provision of homes for doctors; the municipality provides the ground and a large amount of the manpower for the building. The administration of these houses, which include facilities for primary health centres, is under the control of provincial councils. They are placed at the disposal of the medical officer of health of the district, who has two or three rooms for his medical work and five or six for his personal use; he pays a monthly rent not exceeding 2% of the cost of the house, and this is set aside for repairs and upkeep. Each is equipped with examination facilities and everything necessary for emergency operations; all medicaments are supplied by the municipality. So far 200 of these houses have been built, and by the end of this year there should be over 500.

PROGUANIL-RESISTANCE IN MALAYAN STRAINS OF PLASMODIUM VIVAX

BY

T. WILSON, M.B., D.P.H.

Institute for Medical Research, Federation of Malaya

D. S. MUNRO, M.B., M.R.C.P.

Captain, R.A.M.C.; Physician, Military Hospital, Kinnara, Kuala Lumpur

AND

D. R. RICHARD, B.M., B.Ch.

Captain, R.A.M.C.

Proguanil ("paludrine") has been widely used throughout the Federation of Malaya for the prevention of malaria since it first became generally available in 1947. Controlled experiments showed that proguanil in doses of 100–300 mg. once a week was an effective suppressive, and reduced parasite and spleen rates in the semi-immune populations on estates. Overt malaria was usually associated with irregular dosage; transmission, however, was light during the period of these experiments (Institute for Medical Research, 1950).

Proguanil was first used by the Army in Malaya in place of suppressive mepacrine early in 1949, with no apparent change in the malaria sickness rate. The present investigation started as an inquiry into an outbreak of malaria which occurred late in 1950 in a British Army unit engaged in operations against bandits in the Tampin district of the State of Negri Sembilan.

Malaria in the Tampin District

Parts of the Tampin district, and of the surrounding districts, have long been regarded as highly malarious. The Army unit concerned arrived in Malaya in the middle of 1947. The unit headquarters were established in Tampin from then until March, 1950, but detached parties were scattered over a wide area of perhaps 100 miles radius, working in the neighbouring States of Selangor, Pahang, Johore, and Malacca. The incidence of malaria during this period seems to have been low. In March, 1950, the unit was moved to Singapore for about six weeks, returning to Tampin in April, and remaining there until April, 1951, when it left for the Middle East.

The main operational differences between the early period and this later period of twelve months were that the detachments were now all working within a more restricted area, inside a radius of some 30 miles from Tampin, and that the malaria rate for several months was high.

The total strength of the unit was about 600 men, and at any one time perhaps 350 men might be engaged in jungle operations. These figures are merely totals; there was a continual interchange of individuals to and from the unit, and between its various sections. As was the standard Army practice in Malaya, the official suppressive dose was one 100-mg. tablet of proguanil daily.

Four malaria infections occurred between the return from Singapore in mid-April and the end of July, 1950; the sequence of events from then on is shown in Table I.

TABLE I.—Primary Attacks of Malaria (British Troops Only)

Parasite Species	1950					1951				Total
	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.	Feb.	Mar.	Apr. 1-9	
<i>P. falciparum</i>	2	1	3	9	9	4	1	3	3	35
<i>P. vivax</i>	4	2	1	7	7	2	3	3	0	29
Total	6	3	4	16	16	6	4	6	3	

FIG. 1.—Treatment chart of Case 1. *P. vivax*.

*Asexual parasites in thick blood films: + = Between 1-10 parasites per thick film field. ± = Less than 1 parasite per field, more than 1 in 10 fields. o = Less than 1 parasite per 100 fields, more than 1 in 100 fields.

The sudden increase in November and December, 1950, and most of the cases occurring thereafter, came from two detachments which had recently started nightly patrols along one particular section of the main railway line.

During the period of just over nine months from July 1, 1950, to April 9, 1951, the Tampin unit, from a strength of about 600 men, supplied 67 admissions for primary attacks of malaria to the Military Hospital at Kuala Lumpur, while other units totalling several thousands supplied only 34 fresh attacks during the same period. The maximum number from any one other unit was eight, and five of these had occurred in one month, October, 1950, from a party operating near the border of the Tampin district. The preponderance of attacks from the Tampin unit was most striking, and caused considerable debate. Either the suppressive discipline was poor or there was something unusual about the malaria parasites of the Tampin district.

The emergence in this area of strains of falciparum malaria resistant to treatment with proguanil had been reported by Edeson and Field (1950). Although the proportion of resistant falciparum infections had increased during the year 1950, haphazard suppression was still regarded as the most likely cause (Institute for Medical Research, 1951). Vivax infections resistant to proguanil treatment had not been encountered; and there had been no indication of any general failure of suppressive proguanil in the civilian population.

Naturally enough, however, suggestions were made that the high malaria rate of the Tampin Army unit might be due, not to irregular suppression, but to infection with parasites which were resistant to prophylactic proguanil. These suggestions were reinforced by the occurrence of 10 primary attacks (5 falciparum, 5 vivax) late in 1950 among men who had arrived in Malaya, after a thorough check of the unit's suppressive discipline had been carried out. None of these 10 men had been in the country for more than three months at the time of his attack; one had been here for only four

weeks, and two for only six weeks. So far as could be ascertained, they had taken suppressive proguanil, regularly, and nine of them had proguanil present in their urine on the day when first seen by one of us (D. R. R.). Unfortunately this test merely confirmed that proguanil had been taken in the few days immediately preceding; the stories of continuous regular suppressive dosage remained "not proven."

Until January, 1951, there was no proof that any of these infections were proguanil-resistant. Proguanil in the Army was being used solely as a suppressive; acute malaria was treated with mepacrine and/or quinine. The Army medical authorities readily agreed to a proposal that one of us (D. S. M.)

should treat vivax infections with proguanil to obtain information about their response to treatment.

The next three patients with acute vivax malaria admitted from the Tampin unit were given a course of 300 mg. of proguanil daily for seven days, after which they immediately reverted to the suppressive dosage of 100 mg. daily, and returned to their unit. Clinical response to treatment was good, but all three were readmitted to hospital with febrile and parasitological relapses 11, 16, and 17 days respectively after resumption of the suppressive dosage. All affirmed that no doses had been missed; none of them had been out on operations since their discharge from hospital, and it seemed that the dose of 100 mg. of proguanil daily had failed to prevent these relapses.

A more strictly supervised investigation was clearly desirable, but unfortunately only three more vivax infections could be so treated before the unit left Malaya; their history is recorded below.

Procedure.—The original diagnosis was made in the Military Hospital laboratory. Once this had been established, duplicate thick blood films were taken daily and stained with Field's rapid stain; one set of these was examined by one of us (T. W.). It will be noted that Cases 1 and 3 were under observation in hospital for four days and seven days respectively before parasites were detected;

FIG. 2.—Treatment chart of Case 2. *P. vivax*.

FIG. 3.—Treatment chart of Case 3. *P. vivax*.

during this time no antimalarial drug was given. Proguanil dosage was 300 mg. daily for seven days, after which it was reduced to 100 mg. daily, and the patients remained in hospital under observation. Doses were given by the ward sister, and tests for proguanil in the urine were carried out frequently by the hospital laboratory.

Case Notes

Case 1 (Fig. 1).—Aged 21. In Malaya two and a half years. No previous history of malaria. Ill four days before admission, and blood film taken before being sent to hospital reported negative. Suppressive dosage said to be regular; proguanil present in urine when admitted to hospital.

Case 2 (Fig. 2).—Aged 28. In Malaya two and a half years. History of seven attacks of malaria in past five years, last attack being just over two years earlier. Ill four days before admission. Suppressive dosage said to be regular, but no urine test on day of admission was made.

Case 3 (Fig. 3).—Aged 19. In Malaya three months. No history of malaria. Ill six days before admission, and blood film taken before being sent to hospital reported to contain a few young trophozoites, probably *P. vivax*, but parasites not detected in hospital until seven days later. Suppressive dosage said to have been regular since day after arrival in Malaya; proguanil present in urine on day of admission.

Comment on Cases 1 to 3

All three patients showed a good clinical and parasitological response to the first treatment course of 300 mg. of proguanil daily for seven days. Despite this, parasites reappeared in each of them after 7, 12, and 13 days respectively on the daily dose of 100 mg. of proguanil, duly followed a day or two later by the recurrence of fever. Although Cases 2 and 3 were given 400 mg. of proguanil daily for the second treatment course, parasite clearance was somewhat slower.

We had hoped to treat a comparative series of vivax infections from other areas, but there were not enough cases; only two others have so far been treated. In both there was a good response to a dosage of 300 mg. daily for seven days. Both were kept in hospital for 20 days after resuming the suppressive dose

of 100 mg. daily, and so far 120 days have passed with no indication of a relapse.

The unit which took over the Tampin camp and operational areas in April, 1951, was warned of the necessity for rigorous suppressive discipline. No malaria infections occurred during April and May, but the figures since are those given in Table II.

By contrast with the previous year, however, 1951 has seen an increase of malaria among various other Army units in different parts of the country. Staff changes and other reasons unfortunately cut short our therapeutic experiments, and only one vivax malaria patient from the new unit in Tampin could be similarly observed in hospital.

TABLE II

Parasite Species	1951					
	June	July	Aug.	Sept.	Oct. 1-16	Total
<i>P. falciparum</i>	3	4	3	12	0	22
<i>P. vivax</i>	1	4	1	13	0	19
Total	4	8	4	25	0	41

Case 4 (Fig. 4).—Aged 24. In Malaya 10 months; in Tampin district two and a half months. No history of previous malaria. Ill four days before admission. Proguanil suppression said to have been regular, and proguanil present in urine when patient admitted to hospital.

Comment.—Treatment with 300 mg. of proguanil daily for 10 days gave rather slow parasite clearance in the primary attack. Parasites reappeared after only nine days on the suppressive dose of 100 mg. daily, followed three days later by onset of fever and symptoms; parasites this time persisted throughout a course of 400 mg. daily for 10 days. Reduction of dose to 100 mg. for just one day resulted in an immediate increase in parasites, followed next day by a fresh rise of temperature to 104° F. (40° C.); the attack was then terminated with quinine. This infection was more obviously resistant to proguanil therapy than any of the earlier ones; and apparently had been contracted in the same area.

FIG. 4.—Treatment chart of Case 4. *P. vivax*.

Discussion

The occurrence of malaria in persons taking suppressive drugs can be explained in various ways. Fairley *et al.* (1946b), after exhaustive investigation of a large-scale outbreak among troops taking suppressive mepacrine ("atebrin") in the Aitape-Wewak area of New Guinea, decided that both irregular dosage and relative resistance to mepacrine were involved. But resistance to a purely schizonticidal drug like mepacrine presents fewer problems than resistance to proguanil. Fairley *et al.* (1946a) concluded that mepacrine and other schizonticides had no action on the pre-erythrocytic stages of the human malaria parasites; their suppressive effect was due to their action on the asexual parasites reaching the blood at the end of the incubation period. If these blood forms become resistant, then ordinary suppressive doses will fail to prevent an attack.

The prophylactic action of proguanil, on the other hand, was fundamentally different. Proguanil had a direct effect on the pre-erythrocytic forms, and asexual parasites failed to reach the blood. Working with New Guinea strains, we found that in falciparum malaria the pre-erythrocytic forms were destroyed, that in vivax malaria their development was merely inhibited, and that overt malaria might occur after dosage was stopped. Proguanil was also an efficient schizonticide, producing radical cure of falciparum infections; and, although it did not destroy gametocytes, it sterilized them and prevented their development in the mosquito.

Covell *et al.* (1949) confirmed the lethal action of proguanil on the pre-erythrocytic forms of a Lagos strain of *P. falciparum*, and the sterilizing action on gametocytes; clinical cure of acute malaria was obtained, but the infections were not eradicated, and relapses occurred within a few weeks. Ciuca *et al.* (1948), however, found that proguanil did not invariably destroy the pre-erythrocytic forms of a Rumanian strain of *P. falciparum*.

Resistance to proguanil therefore may show itself in various ways. It may be a resistance of the asexual erythrocytic forms or of the pre-erythrocytic forms or of the gametocytes; and certain strains might prove to be resistant throughout the life cycle.

We can do little to resolve the conflict of opinion between those who hold that the excess of malaria in the two Tampin units was due mainly to irregular prophylaxis, and those who favour the idea of infection with strains resistant to prophylactic proguanil. One of us (D. R. R.) was regimental medical officer of the first unit for its last 18 months in Malaya. He considers that suppressive discipline was fair even before September, 1950, and was good from September onwards; the ten infections mentioned above as occurring in new arrivals after October, 1950, developed, he thinks, despite a regular prophylactic dosage from the time of reaching the country. To this opinion may be added a number of similar complaints from Africa (Davey and Smith, 1949; Bruce-Chwatt and Bruce-Chwatt, 1950; MacLeod, 1951), but proof of regular dosage was unobtainable in many of the examples given. We cannot be certain how many of the Tampin infections were due to irregular prophylactic dosage, but we suggest that some at least may have occurred in men who took their doses regularly.

Reverting to our therapeutic findings, it seems that probably in the first three patients, and certainly in the four observed in hospital, we were dealing with erythrocytic forms of *P. vivax* which were only temporarily suppressed by daily doses of 300 mg. of proguanil, and which could multiply sufficiently to produce clinical and parasitological relapses while 100 mg. daily was still being taken. Malayan strains of *P. vivax* had hitherto proved very sensitive to treatment with proguanil (Institute of Medical Research, 1950),* and the two vivax infections from other areas had

not relapsed over a much longer period. How might this degree of resistance have been produced, and what were the implications?

Experimentally, the erythrocytic forms of both *P. falciparum* and *P. vivax* have been rendered resistant to proguanil treatment by exposing them repeatedly to inadequate doses (Seaton and Adams, 1949; Seaton and Lourie, 1949; Cooper *et al.*, 1950a); but prolonged dosage during the pre-erythrocytic stage of *P. vivax* did not induce resistance in the erythrocytic forms which appeared after dosage was stopped (Cooper *et al.*, 1950b). We think it unlikely that each of our patients was originally infected with a sensitive strain which he then transmuted into resistant forms by widely spaced doses during sporadic bursts of parasitaemia, but this possibility cannot be dismissed entirely; three of the four patients had been in the country for ten months or more, though only one was known to have had malaria before. Such a method of producing resistant erythrocytic forms would seem to be ruled out for Case 3, who had been here for only three months. This man did not arrive in Malaya until December, 1950, by which time a great deal of attention had been paid to the suppressive discipline of his unit. He had no history of previous fever, and the parasite level at which he originally developed symptoms was low, indicating that this was probably a primary attack. We suggest that the balance of evidence is in favour of another hypothesis—namely, that these men had been infected by a strain of vivax malaria whose erythrocytic forms had already developed a partial resistance to proguanil.

Seaton and Adams (1949) and Seaton and Lourie (1949) have proved that when the erythrocytic forms of *P. falciparum* and *P. vivax* have become resistant to proguanil the erythrocytic parasites which appear in fresh victims, after mosquito passage of the infection, are also resistant. It is thus possible that under suitable local conditions mosquitoes may be transmitting strains of malaria whose erythrocytic forms are relatively resistant, as in these patients of ours. Confronted with this possibility, the medical officer in the Tropics wants to know, among other things, whether proguanil-resistance of the erythrocytic forms automatically implies a change in the response of the pre-erythrocytic forms to proguanil prophylaxis. If the erythrocytic forms are resistant, can the pre-erythrocytic forms of that particular strain complete their development despite a regular prophylactic dosage from the time of infection, and will proguanil thus be as powerless to prevent clinical attacks as it is to cure them when they occur?

Oddly enough, the experimental workers have not yet provided an answer to this most important question. The experiments on proguanil prophylaxis with human malaria parasites all seem to have been made on strains which responded well to proguanil treatment of acute attacks; this was so even with the Lagos strain of *P. falciparum* investigated by Covell *et al.* (1949). The only report of a prophylactic experiment with a resistant strain which we have seen is one by Hawking and Thurston (1951) on *P. cynomolgi* in monkeys. Proguanil given shortly before sporozoite inoculation, and daily for seven days afterwards, prolonged the incubation period by only one day in the treated monkey compared with an untreated control. There is unfortunately no indication of how the original proguanil-sensitive strain behaved when treated in the same way.

In Malaya to date, and probably elsewhere, strains of human malaria refractory to proguanil therapy occur only sporadically, yet their appearance has prompted the recommendation that proguanil should not be used by itself for the treatment of acute falciparum malaria. But the drug is being distributed as a suppressive on a very large scale, often without supervision, and there are indications that such resistant strains are becoming more common; the danger, therefore, is that they will become widespread. Before that occurs, the field worker needs to know whether proguanil can still be relied upon as a prophylactic against these strains, or whether he must seek elsewhere for protection. Clearly

*Dr. J. F. B. Edeson (personal communication) reports one resistant vivax infection in April, 1951, in Tampin Hospital, with asexual parasites still present on the seventh day of treatment with 300 mg. of proguanil daily.

we need a controlled experiment in proguanil prophylaxis, comparing proguanil-sensitive and proguanil-resistant strains of human malaria parasites, to decide whether there is in fact any significant difference in their response to regular prophylactic doses.

Summary

Fresh infections of falciparum and vivax malaria occurred late in the year 1950 among British troops in the Tampin district of Negri Sembilan, Federation of Malaya, shortly after they had started night patrols in one particular locality.

A similar incidence of malaria occurred in 1951 among troops from a different unit operating in the same areas.

The troops were on an official suppressive dosage of 100 mg. of proguanil daily, and suppressive discipline was thought to be good.

Treatment of some of the vivax infections revealed that their erythrocytic parasites were only temporarily suppressed by doses of 300 mg. of proguanil daily for 7 to 10 days. Parasitological and clinical relapses occurred 7 to 17 days after reverting to the normal suppressive dose of 100 mg. daily. One of these patients had been only three months in Malaya, and had been on regular suppressive proguanil from the day after arrival.

Possible explanations for these findings are discussed. Irregular dosage cannot be excluded as a possible cause of the incidence of malaria in the Tampin units, but it is thought that some infections may have developed in men who took their suppressive doses regularly. It is suggested that the proguanil-treated vivax patients may have been infected with a strain whose erythrocytic parasites were already partially resistant. If this may happen, as seems possible, then controlled experiments are needed to determine whether resistance of erythrocytic forms also implies that pre-erythrocytic forms may complete their development, and produce clinical attacks of malaria, despite regular prophylactic dosage from the time of infection.

Our thanks are due to Colonel F. Palmer, late R.A.M.C., A.D.M.S. Malaya, for permission to treat these patients; to Colonel D. W. Hughes, late R.A.M.C., Consultant Physician, FARELF, for criticism and advice, and to Brigadier R. Murphy, late R.A.M.C., D.M.S., FARELF, for permission to publish.

CHEMOTHERAPY AND CHEMOPROPHYLAXIS OF MALARIA

CLINICAL TRIALS IN 500 CASES AND MASS PROPHYLAXIS IN A HYPERENDEMIC AREA

BY

AND

M. N. RAI CHAUDHURI, M.B.

(From the School of Tropical Medicine, Calcutta)

With a Statistical Analysis by

S. JANARDAN POTI, M.A.

(From the All-India Institute of Hygiene and Public Health, Calcutta)

During the past three or four years a number of new drugs have been tested at the Calcutta School of Tropical Medicine for their therapeutic and suppressive values in malaria. The patients admitted to the attached hospital were utilized for the purpose, but the main work on the suppressive therapy was carried out in a rural area about 40 miles from Calcutta. A summary of the work is given in Tables II and III.

I. CHEMOTHERAPY

Only those patients who had fever with parasites in the blood and had no antimalarial drug outside were selected for the trials. The blood was examined twice daily (thick film method, using Field (1941) or J. S. B.* stain) until it became negative for asexual parasites, and thereafter once daily throughout the period of hospital observation. Of the 500 cases examined 51% had *P. vivax* and 42% *P. falciparum* infection; the rest had mixed (4.4%) or *P. malariae* (2.6%) infection. The following drugs were tried:

TABLE I.—Schedules of Treatment

No.	Compound Used	Route of Administration	No. of Cases

			500

* One patient also had oral and intramuscular proguanil in addition to intravenous therapy.

1. Proguanil

Effect on Temperature and Parasite.—The usual route of administration was by mouth, and in only a small number of cases was the parenteral method used. Orally, various dosage schedules were tried either in a single dose of 0.1 to 0.8 g. or in divided doses of 0.3 to 0.8 g. given daily over 4 to 10 days. With any of these regimes an acute attack was terminated on the third day in most cases. A daily dose of 0.3 to 0.6 g., however, seemed to produce the best results, and we think that a course of 1.8 g. given over five

*Jaswant Singh and Bhattacharji (1944).

Control (quinine for acute attacks only)	VI	11.32 (265)	15.03 (173)	36.87 (179)	14.57 (199)	17.4 (224)	6.82	9.32	15.57	13.33	22.2 (216)	62.98	61.2	50.6	54.2	55.4

The drugs were administered for 26 weeks from July to December in the first five groups and the sixth group served as a control. The observations were carried out through two transmission seasons and are referred to here as 1948-9 and 1949-50 experiments. The parasite rate, malaria incidence rate, and spleen rate are all expressed in percentages. The figures in parentheses indicate the number of cases examined at different stages of the experiment.

* The higher incidence rate in these two groups may be partly due to the mode of collection of data; they were paid two visits a week as compared with one visit a week in the other groups.

days—that is, 0.6 g. in two doses on the first day and 0.3 g. on the next four days—is sufficient to terminate a malarial attack in an average case unless one encounters a refractory strain. A higher dose has not been of any advantage either in controlling the acute attack or in preventing relapses. For reducing the relapse rate of vivax or malariae infection, however, it should be combined with pamaquin, or be followed by weekly proguanil (0.3 g.) as long as possible. We found the drug about equally active, though relatively slow, against falciparum and vivax types of parasites. It has no influence on the appearance of crescents in the peripheral blood; these tend to persist for a long time, the maximum period noted being two months.

Absorption and Excretion.—For determination of proguanil concentration in the blood the hydrolytic method of Spinks and Tottey (1946) was used. The level of proguanil varied with different individuals, but in general it was proportionate to the dose of the drug. There was a rapid rise in the concentration of the blood after four hours; it was reduced nearly to half on the second day, and usually by the fourth day it was down to negligible figures. About the same kind of result was obtained after intramuscular administration. It was also observed that the drug disappeared from the urine generally in four to five days, most of it being excreted during the first 48 hours. The total excretion varied from 37 to 54% of the drug administered.

Toxicity.—No toxic reactions were noticed except in patients who were having large amounts of the drug. With 0.8 g. given in a single dose or in daily divided doses, gastro-intestinal irritation with nausea, vomiting, diarrhoea, and griping was the commonest untoward reaction, but renal irritation was noticed in two patients (0.2 g. six-hourly for four days), one of them having frank haematuria with pain in the loins. The withdrawal of the drug gave prompt relief, but in some patients the treatment was continued without any ill effect. In a few cases (0.3 g. twice daily for 10 days) gastric irritation was noticed towards the end of the course, and on this account treatment was discontinued about the seventh day.

Relapses.—The working of the relapse rate is rather difficult in India, where people are constantly exposed to the risk of infection. Many of the relapse cases, however, developed the attack in the hospital or under conditions where the chance of reinfection was unlikely. Owing to the unavoidable uncertainty, we have lately laid more stress on the early relapses and kept most of our patients in hospital for at least a month under observation. Judging in this way, we found that early relapses were more infrequent with divided proguanil dosage given for 4 to 10 days than with single doses. But even with proper dosage the cases that have been followed up for three to six months have shown a relapse rate of the order of 40%. The actual relapse rates for different observation periods are shown in Table I, from which it will be evident that the single-dose treatment

always leads to a high early relapse rate, indicating the inadequacy of that method of treatment. We are therefore of the opinion that the single-dose treatment with proguanil should be abandoned.

Resistance to Proguanil.—We have encountered some cases of falciparum infection that proved refractory to proguanil. In one case the drug had no effect on the fever and parasites, and resistance of the particular strain was also shown in a second volunteer who was inoculated with the blood of the first patient and developed malaria which did not respond to intensive proguanil therapy. In another case there were repeated early relapses, indicating that the parasite was resistant and could not be completely eradicated with proguanil. Besides these we had two fatal cases of malaria: (1) a girl of 9 admitted in a restless and delirious state; and (2) a man of 75 with 35.6% of red cells infected with falciparum rings (some red cells containing two, three, or four rings) and a few schizonts and crescents. The girl had two intravenous injections, 0.1 g. each, before she died 16 hours after admission, while the old man had 1.4 g. of proguanil (parenterally and orally) in the course of the 34 hours he was alive in the hospital. A necropsy in this case showed intense proliferation of the parasites in the internal organs, though their number in the peripheral blood had been reduced. The first patient was severely ill and the second had a very heavy infection, so it is difficult to say what would have happened if more potent antimalarial drugs had been used.

Parenteral Proguanil.—This was given intravenously or intramuscularly, 12 cases by each method, and the results are shown in Table IV.

TABLE IV.—*Parenteral Proguanil: Effect on Temperature and Asexual Parasites*

Route	Total Cases	Infection					Last Day of Fever					Last Day of Parasites				
		F.	V.	M.	V.	F.	1	2	3	4	5	1	2	3	4	5
		F.	V.	M.	V.	F.	1	2	3	4	5	1	2	3	4	5
I.V.	12	9	2	0	1	0	1	4	5	0	0	2	0	7	3	0
I.M.	12	3	6	2	0	1	2*	1	5	3	1	0	1	5	5	0

* One of these patients, a case of quartan malaria, received the drug in the apyrexial period and the next paroxysm was suppressed.

Intravenous Proguanil.—Proguanil acetate or lactate was tried as an experimental measure in a series of 12 cases of malaria, all except two of which had falciparum infection. Two of the patients in this series, already mentioned above, died. The injections (up to 400 mg. at a time) were well tolerated by some, but two patients had phlebitis of the injected vein (which subsided in a few days). One had a severe reaction (collapse) after the injection, and another developed

symptoms suggestive of encephalitis, though it could not be definitely said whether it was the effect of the drug or of the disease. The symptoms eventually cleared up within about two months.

Intramuscular Proguanil.—Proguanil lactate (0.1 g. in 2-ml. ampoules) was tried in a single dose varying from 0.1 to 0.3 g. The results were somewhat like those obtained with oral proguanil. All the three *P. malariae* cases in this series responded to a single injection of 0.1 g., and no recrudescence occurred within four to six weeks while they were in the hospital. One of them had regular paroxysms for one year interrupted only for a fortnight by quinine, with a splenic enlargement to 9 in. (23 cm.) below the costal margin. The injection controlled the paroxysm and the patient was discharged after a month with a spleen reduced to only 3 in. (7.5 cm.) below the costal margin. The intramuscular injections were painful (more than with quinine), but the pain, local induration, and tenderness did not usually persist beyond the third day and left no sequelae, except in one case in which there was a local blister formation which gradually dried up.

2. Quino-Pamaquin, Proguanil-Pamaquin, and M.5943

These drugs were tried in 60 vivax and one malariae infection, mainly with the object of ascertaining the relapse rates. Quino-pamaquin is already a well-known remedy for the radical cure of recurring vivax malaria, and was adopted as a standard for comparison. M.5943 is a new synthetic compound. During their study of the antimalarial properties of diguanide substances related to proguanil, Curd, Davey, Hendry, and Rose (1950), of the Research Laboratories of Imperial Chemical Industries, Manchester, obtained the impression that weighting the benzene ring augmented activity. They therefore prepared a number of compounds in which *di*-substitution was made in the benzene ring. Dihalo-substitution in positions 3 and 4 proved particularly favourable for antimalarial activity. A representative compound, *N*,3,4-dichlorophenyl-*N*,5-isopropyl diguanide (given the laboratory number M.5943), was chosen for trial in human malaria. M.5943 differs from proguanil only in having an extra Cl-group in position 3 of the benzene ring. Its constitution is:

M.5943 was tested against *P. gallinaceum* and *P. relictum* (Algerian strain) by Davey (1946a, 1946b) and was found to be much more active than proguanil against both the blood forms and the exoerythrocytic forms of these parasites. We are reporting here the results of treatment with M.5943 in vivax malaria as compared with combined courses of quino-pamaquin and proguanil-pamaquin.

TABLE V.—M.5943, Quino-Pamaquin and Proguanil-Pamaquin in Vivax Malaria

	Quinine 5 gr. (0.32 g.) + Pamaquin 10 mg. (Base) t d s. for 10 Days	Proguanil hydro- chloride 0.3 g. + Pamaquin 10 mg. (Base) b d. for 10 Days	M.5943 20 mg t d s. for 10 Days
No. of cases	13 (V.)	14 (V.)	18 (17 V. + 1 M.)
Average duration of fever (days)	1.1	1.8	1.8
Average duration of parasite in blood (days)	1.8	2.0	2.2
Gametocytes:			
Cleared in 3 days	100%	86%	67%
Persisted for 4 or 5 days	Nil	14%	33%
Relapse rate (average period of observation, 3 months)	8%	29%	17%

Table V shows that the best immediate result was obtained with quino-pamaquin, both proguanil-pamaquin and M.5943 being slower and equal in action. M.5943 appears to be

rather slowly active against *P. malariae*, the temperature and parasites in the single case having persisted for five days. All the three drugs cleared the peripheral blood of the vivax or malariae gametocytes, and this property was most marked with quino-pamaquin, which was also better than the other two in respect of both immediate action and relapses. The difference in the gametocidal property of the first two combinations, however, may be due to the higher dose of pamaquin—namely, 30 mg. daily used in the first as compared with 20 mg. in the second.

Relapses.—The relapse rate in a follow-up for an average period of three months in the 45 cases observed in 1949 worked out at 17% (3 cases) for M.5943, 29% (4 cases) for proguanil-pamaquin, and 8% (1 case) for quino-pamaquin. Another subclinical relapse in the second series was detected accidentally by the development of febrile malaria in the recipient of a blood transfusion from the said case. If this is included the relapse rate in the proguanil-pamaquin series rises to 36%. If all the 30 cases (including 16 cases treated in the previous year) of the proguanil-pamaquin series are taken together, however, the relapse rate works out at 20%. There is no significant difference in the interval of freedom of attack prior to relapse in the three groups.

Toxicity.—Two cases in the proguanil-pamaquin series showed rather severe toxic reactions (nausea, vomiting, palpitation, and depression) and could not take the full course. No significant side-effect was noticed with quino-pamaquin. In the M.5943 group seven patients had toxic reactions—namely, nausea, vomiting, and/or abdominal pain. One patient complained of bleeding from the gums and another of dysuria during the course, but it cannot be definitely stated that they were entirely due to the drug. The treatment had to be interrupted for a day or two in a few cases for these reactions, and was then resumed in the same or slightly reduced dosage.

3. Chloroquine

Effect on Temperature and Parasites.—Chloroquine was tried in either single or divided doses in a series of 75 patients. The clinical response was very prompt with each regime, and fever and parasitaemia were controlled by the third day in all except one case. With 1.5 g. (base) in a single dose or 1.25 g. in divided doses, 96% became afebrile and 80% parasite-free in two days in a series of 50 patients: these figures were 84% and 100%, respectively, in another series of 25 patients treated with a single dose of 0.5 g. We have not had such an excellent result with any other anti-malarial drug. We found it somewhat more active against vivax than against falciparum infection.

TABLE VI.—Action of Chloroquine on *P. falciparum* and *P. vivax*

Infection	No. of Cases	Last Day of Fever				Last Day of Asexual Parasite			
		1	2	3	4	1	2	3	4
<i>P. falciparum</i>	29	17 59%	7 24%	5 17%	0	12 41%	11 38%	5 17%	1 3%
<i>P. vivax</i>	41	23 56%	17 41%	1 3%	0	20 49%	17 41%	4 10%	0

It will be seen from Table VI that, while fever had subsided in 83% and asexual parasites disappeared in 79% in two days in falciparum infection, the corresponding figures from vivax infection are 97% and 90%. The drug has little or no action on gametocytes, the crescents having been found up to 22 days after treatment.

Toxicity.—Some untoward effect of the drug was observed in 5 of the 50 cases (10%) treated with 1.25 or 1.5 g. of the basic drug. Complaint was made of one or more of the following symptoms, which usually disappeared in two days; insomnia, gastro-intestinal irritation, pruritus (especially in the hands and feet), and pain in the lower abdomen, genitalia, and thighs (1 case). Another patient, not included in this series, had epileptiform fits after taking the drug.

Relapses.—Four patients relapsed out of 20 who had 1.5 g. (single dose) or 1.25 g. (divided doses) and who could be followed up for one to seven months: two with falciparum infection after 30 and 45 days, and two with vivax infection after 45 and 210 days. Two (one falciparum and one vivax) out of 12 patients given a single dose of 0.5 g., and who were followed up to three months, relapsed after 53 and 49 days respectively. None of the patients had an early recrudescence in the hospital with either regime, unlike the cases under proguanil. In fact, relapses were much less common with chloroquine.

4. Camoquin

Camoquin is almost as potent a drug as chloroquine. A single dose of 0.5 g. of the basic drug terminated fever and cleared the parasites in two days in 86% and 83% of the 52 cases respectively. This single-dose treatment was better than the divided dose of 0.1 g. twice daily for three days, which in a series of 27 cases gave the corresponding figures as 74% and 81%. It is almost equally effective against vivax, falciparum, and malariae infections. It has no action on crescents, which were seen in the blood up to 26 days, but the vivax and malariae gametocytes disappeared in one to five days.

Toxicity.—The drug was well tolerated and no untoward symptoms were noticed even in cases with severe anaemia.

Relapses.—Here also the single-dose treatment gave better results. Out of 33 patients who had a single dose of 0.5 g., 8 (3 falciparum and 5 vivax) relapsed, while 6 out of 8 patients who had 0.6 g. over three days relapsed, in each case after an interval varying from 2 to 30 weeks. All of them were under observation for one to eight months. The high relapse rate and lower potency of the divided dose would appear to be due to inadequacy of dosage, and will, we think, be improved by giving an initial loading dose.

5. Chloroquine or Camoquin in Combination with Proguanil

Since infections with *P. falciparum* may prove refractory to proguanil alone, we used that drug in combination with chloroquine or camoquin in two series of cases, and 21 patients have so far been treated in this manner. The effect on temperature and parasitaemia is shown in Table VII.

TABLE VII.—Effect of Combined Chloroquine-Proguanil and Camoquin-Proguanil on Temperature and Parasitaemia.

Drug and Dose	Infection	No. of Cases	Last Day of Fever				Last Day of Parasitaemia (Asexual)			
			1	2	3	4	1	2	3	4
Chloroquine, 0.5 g. base on 1st day, and proguanil hydrochloride, 0.3 g. b.d., for next six days	F. V.	11 2	7 1	3 1	1 0	0 0	1 1	8 1	2 0	0 0
Total		13	8	4	1	0	2	9	2	0
			92.5%				84.6%			
Camoquin, 0.5 g. base on 1st day, and proguanil hydrochloride, 0.3 g. b.d., next 6 days	F. V.	6 2	1 0	4 1	1 1	0 0	3 0	1 1	2 1	0 0
Total		8	1	5	2	0	3	2	3	0
			75%				62.5%			

It will be seen that this method of treatment rapidly terminated the malarial attack. The results are comparable to those obtained with single doses of camoquin or chloroquine alone. But proguanil alone would have been slower in action, and its reinforcement on the first day by a single dose of chloroquine or camoquin seems to have had a greater effect than quinine or mepacrine in similar conditions.

There were no toxic reactions, and only one case in the camoquin-proguanil series out of the 21 cases treated relapsed after three weeks in a follow-up period of 15–53 days in the hospital.

6. Indigenous Drugs

Neochin, which is dicinchonine carbonate, had a poor antimalarial property, and the other drugs were useless.

Conclusion

Chloroquine and camoquin are the two outstanding drugs in the treatment of malaria. Even with a single dose they can effect a clinical cure in most cases in two days, with disappearance of asexual parasites. Proguanil is also effective, but has a slower action, and resistant falciparum cases are occasionally encountered. The optimum effective dose in our cases has been chloroquine (base), 0.5 g. immediately, 0.25 g. after six hours, and 0.25 g. on the second and third days; camoquin (base), 0.5 g. (or three 0.2 g. tablets) in a single dose; and proguanil hydrochloride, 0.3 g. twice, daily on the first day and 0.3 g. once daily for the next four days. The toxic effects of proguanil are usually insignificant, but may result from large doses. So far no toxicity has been observed with camoquin, while about 10% of chloroquine cases had temporary untoward reactions in the doses used. These drugs, however, do not solve the problem of vivax relapses, which can at present be reduced by giving quino-pamaquin, which is more effective than proguanil-pamaquin, or suppressed by weekly doses of one of the above drugs. M.5943 has no advantage over other antimalarials.

II. CHEMOPROPHYLAXIS

Prophylactic trials were carried out in two successive years, 1948 and 1949, in a hyperendemic rural area, about 40 miles (64 km.) from Calcutta, comprising 10 villages with a population of 1,458. The people were mostly land workers in a poor nutritional condition. The overall spleen and parasite rates were 62.8% and 10.7% respectively, while the corresponding rates for children under 10, who formed nearly one-third of the population, were 58.5% and 17.4%. The work was started with five groups of the population each consisting of about 250 people—four having proguanil, camoquin, or chloroquine (groups I to IV; see Table III), and one serving as control (group VI). In 1949, in addition to these five groups, an extra group (V) was given bi-weekly quinine prophylaxis, and a subgroup (IIIA) of about 50 people had camoquin prophylaxis in a reduced dosage. The details are shown in Table VIII.

The drugs were administered throughout the transmission period from July to December. Blood was examined every two or three months, but the spleen was examined only at the beginning and end of the prophylactic period. The incidence of malaria in those taking the drugs was judged by examining the blood of those who had fever. To the control group no drug was administered except a few doses of quinine to control the acute attacks. No anti-mosquito measures were adopted in the whole area.

Parasite Rate

Compared with the control group malaria was definitely under check, the parasite rate remaining more or less low according to the drug used. In May, 1948, prior to the first experiment, the average infection rate in these villages was 10 per 100. In November, 1948, this rose to 37 in the control group (October and November are here the usual peak

TABLE VIII.—Schedule of Chemoprophylaxis

Group	No. of Subjects	Drug Used and Frequency of Administration	Dose			Year of Trial	Initial Spleen Rate %	Initial Parasite Rate %
			> 10 yrs.	4-10 yrs.	< 4 yrs.			
I	235	Proguanil hydrochloride twice weekly	0.1 g.	0.05 g.	0.03 g.	1948-9	55.4	12
II	276	Proguanil hydrochloride once weekly	0.3 "	0.2 "	0.1 "	1948-9	72.8	9.42
III	246	Camoquin* once weekly	0.2 "	0.1 "	0.05 "	1948-9	64.2	10.57
IV	227	Chloroquine* once weekly	0.25 "	0.125 "	0.062 "	1948-9	57.7	7.9
V	289	Quinine sulphate twice weekly	5 gr.	2½ gr.	2½ gr.	1949	53.4	5.19
VI	265	No drug—prophylaxis (control)				1948-9	61.2	11.32

* Dosage of camoquin and chloroquine is expressed in base.

period of malaria), while the parasite rates in the treated groups varied from 2 to 6, the best results being obtained with camoquin and chloroquine. As regards proguanil, there was some superiority of the bi-weekly group (I) to the weekly regime (II). In 1949 the results were still more remarkable. The control group showed a parasite rate of 15.57 in the month of November—a much lower peak than in the previous year owing to lessened severity of malaria that year or to unexplained factors, whereas the corresponding figures for chloroquine (IV), camoquin (III), and bi-weekly proguanil (I) were 0.00, 0.67, and 2.86 respectively. With the last regime, however, there was a rise in the parasite rate in September, 1949, by almost 50% above the rate in July, 1949, the cause for which is not understood.

In striking contrast to the results in the three groups mentioned above, the weekly proguanil regime (II) was less effective, with a parasite rate of 7.65 against the previous year's figure of 5.73, which in itself was high enough. As regards quinine, which was first used in 1949, the reduction of parasite rate from 5.19 in July to 4.04 in November is not itself significant, but there is no doubt that this drug exerted some control, for the parasite rate in the control group rose from 6.82 to 15.57 in the same period of time. The conclusion, confirmed statistically, was that chloroquine and camoquin prophylaxis offered the best protection. Of the two proguanil groups the bi-weekly regime (I) definitely gave better results than the weekly regime (II), though both were inferior to groups III and IV. The results obtained with bi-weekly quinine prophylaxis (V) were somewhat intermediate between the two proguanil regimes in respect of the parasite rate, but the difference was not statistically significant.

It has been mentioned that, in addition to the main camoquin group (III) receiving 0.2 g. of the basic drugs weekly, a subgroup was included in 1949 consisting of 50 subjects who were given 0.1 g. of camoquin (base) every week (IIIA). The parasite rates in the latter were similar to the main camoquin group (III). As the malaria incidence rate per 100 was 4.00 in group IIIA as compared with 3.12 in group III and 62.98 in group VI (control), it would appear that the effect of 0.1 g. of camoquin weekly is the same as that of 0.2 g. But, the number of subjects taken in group IIIA being very small, the similarity of its action with group III cannot be regarded as statistically significant. Nevertheless it shows that camoquin in such small dosage as 0.1 g. weekly can give considerable protection to persons exposed to malarial infection. It is possible, from the parasite rates in the control and treated groups, to calculate the degree of freedom from attacks afforded by each drug. Table IX gives the number of persons who would be freed from parasites by each of the drugs out of 100 who carry parasites in their blood.

The month of November has been chosen from each group, as this is the peak period for malaria.

TABLE IX.—Percentage of Infected Persons Given Protection by Various Drugs

	Nov., 1948	Nov., 1949
Proguanil (twice weekly) ..	88	82
" (once weekly) ..	84	51
Camoquin (once weekly) ..	95	96
Chloroquine (once weekly) ..	93	100
Quinine (twice weekly) ..	—	74

Spleen Rate

The reduction of the spleen rate is best seen from Table X.

TABLE X.—Showing Effects on the Spleen Rate

Group	May, 1948	Feb., 1949	Oct., 1949	Feb., 1950
I	55.4	24.4	33.0	26.8
II	72.8	35.6	33.5	26.0
III	64.2	16.4	26.3	12.4
IV	57.7	18.2	25.7	8.8
V			53.4	43.1
VI	61.2	50.6	54.2	55.4

In keeping with their effects on the parasites, camoquin and chloroquine had considerably reduced the spleen rates—namely, to 12.4 and 8.8% respectively in February, 1950 (for convenience final spleen examination was made in February each year)—and these figures are lower than in the previous year. Curiously enough, though proguanil acted differently on the parasites according to the dosage scheme, the spleen rates in both groups were about the same—namely, 26% in February, 1950 (see Chart). Quinine was undoubtedly least effective in respect of the spleen rate, which was 43.1% in February, 1950, the initial rate being 53.4%. This would throw doubt on the efficacy of quinine prophylaxis in spite of its effect on the parasite rate. The control group, in accordance with our expectations, showed a persistently high rate, never falling below 50%.

* OCT. '49 in CASE OF GROUP V.

- To arrive at a proper evaluation of the drugs so far as the splenic enlargement is concerned, a statistical analysis was made of those subjects who had an enlarged spleen at the beginning of the experiment and those who had no such enlargement. The results in the former are similar to the overall figures shown above. In the latter, whose spleen was initially not palpable, all the treated groups showed prevention of splenic enlargement in varying degrees (see Table XI).

TABLE XI.—Showing the Effect of the Drugs on the Spleen of Patients who had no Initial Splenic Enlargement

Group	1948-9 Experiment		1949-50 Experiment	
	No. of Cases with No Palpable Spleen in May, 1948	Percentage Showing Enlargement in Feb., 1949	No. of Cases with No Palpable Spleen in Oct., 1949	Percentage Showing Enlargement in Feb., 1950
I	73	15	117	11.1
II	32	12	130	8.5
III	47	0	85	4.7
IV	31	0	90	1.1
V	—	—	68	6.3
VI	56	27	59	27.1

All the treated groups show significantly lower spleen rates compared with the control, in which 27% developed splenic enlargement after the transmission season. It was striking that in 1948-9 the spleen was not palpably enlarged at the end of the experiment in any of those subjects in the camoquin (III) and chloroquine (IV) groups who had not shown it at the beginning. In 1949-50 the lowest spleen rate was recorded in group IV, and is significantly less than all the other groups except III, which occupies an intermediate position between group IV and other treated groups. It may therefore be concluded that all the prophylactic regimes were effective in preventing splenic enlargement, chloroquine being most valuable in this respect.

Malaria Incidence

The data for malaria incidence during the prophylactic period were more accurately collected in the second experiment. Nevertheless they should be regarded as only approximate, because there were difficulties in obtaining correct information from the villagers. The incidence rate of malaria in those who were under prophylactic treatment was 21.54% with bi-weekly proguanil, 12.28% with weekly proguanil, 3.12% with camoquin, 2.27% with chloroquine, and 26.1% with quinine, as compared with 62.98% in the control group. It should be mentioned that only parasite-positive cases have been taken in the above analysis, and a person suffering more than once has been counted as one.

We might say that all the treatments were effective in reducing the incidence rate in so far as the rates recorded for these were significantly lower than that of the control group. Group III and group IV treatments were definitely better than all the others. There was no statistical evidence of difference amongst the other treated groups (I, II, and V). The higher rates in groups I and V may have been partly due to the method of collecting the data. These groups were paid two visits a week as compared with one visit in the other groups. This has undoubtedly inflated the figures in groups I and V to some extent. But, even taking this fact into consideration, camoquin and chloroquine show the best results in the prevention of malaria.

Conclusion

As in chemotherapy, so in chemoprophylaxis, chloroquine (base, 0.25 g. weekly) and camoquin (base, 0.2 g. weekly) have proved superior to proguanil (salt, 0.3 g. weekly or 0.1 g. bi-weekly). They afforded high protection and reduced splenomegaly, thereby improving the general health of the population and increasing the working capacity.

In spite of the fact that the people were living in poor economic conditions, and in the absence of any other

antimalarial measures, there was marked reduction in the incidence of malaria, which varied according to the drugs used. Until anti-mosquito measures are possible chemoprophylaxis should have an important place in the suppression of malarial fever. It causes no inconvenience—a dose once or twice a week is enough, and it need not be costly. What is wanted is malaria discipline, but, once impressed, the villagers are willing to co-operate.

We wish to thank Dr. S. Ghosh, Mr. B. N. Dutt, and Mr. C. L. Mitter for their help in this work. Thanks are also due to Imperial Chemical Industries (India) Ltd., Parke, Davis and Co., and the Malaria Department of the National Institute of Health, U.S.A., for the liberal supplies of proguanil and M.5943, camoquin and chloroquine respectively.

A. C. THACKRAY, M.A., M.D.

Assistant Pathologist

The Middlesex Hospital, London

Enlargement of the liver and spleen is an uncommon mode of presentation of abdominal tuberculosis. The four cases reported below illustrate the clinical appearance of this condition and, in addition, demonstrate the association of blood disorders with hepato-splenic tuberculosis.

Case 1

A woman aged 69 had had enlarged lymph nodes excised from her neck at the age of 6 years and a tuberculous right axillary lymph node removed when aged 36. For one year she had suffered from lassitude, haemorrhoids, and an uncomfortable swelling of the abdomen. The cardiovascular, respiratory, and nervous systems were normal. The spleen was hard, painless, and enlarged almost to the umbilicus, with a firm raised swelling $2\frac{1}{2}$ by $1\frac{1}{2}$ in. (6.4 by 4.4 cm.) in size palpable on its surface. The liver was enlarged 1-2 in. (2.5-5 cm.) below the costal margin. She was afebrile and of a steady weight. A blood count on admission showed: Hb, 63% (9.1 g.); red cells, 4,500,000 per c.mm.; white cells, 30,000 per c.mm. (neutrophils 86%, lymphocytes 4%, monocytes 3%, eosinophils 1%, metamyelocytes 2%, myelocytes 4%); platelets, 320,000 per c.mm. The blood film revealed hypochromia, microcytosis, and anisocytosis. The sternal marrow gave a total nucleated cell count of 200,000 per c.mm. (myeloblasts 3%, pre-myelocytes 2%, myelocytes 32%, metamyelocytes 10%, polymorphonuclears 38%, lymphocytes 1.5%, monocytes 0.7%). The myeloid/erythroid ratio was 9:1. These figures supported the clinical diagnosis of chronic myeloid leukaemia. After a course of deep x-ray therapy to the spleen her leucocyte count was 13,500 per c.mm., but rose subsequently to 28,000-50,000 per c.mm.

Six months later the patient was readmitted with severe pain in the left loin. She was ill, had lost 6 lb. (2.7 kg.) in weight, and ran a fever up to 102° F. (38.9° C.). The spleen reached beyond the umbilicus and was very tender. The liver was enlarged four fingerbreadths below the right costal margin. A blood count showed no anaemia. The leucocyte count was 15,900 per c.mm. (neutrophils 94%, lymphocytes 2%, monocytes 2%, eosinophils 2%). One week after admission ascites developed and a left pleural effusion collected shortly before her death.

Post-mortem Examination

The myocardium was pale and fatty. The left pleural space contained 2½ pints (1.4 litres) of yellow fluid, with some collapse of the lower lobe of the lung, roughening of the pleural surface, and slender fresh adhesions over the upper lobe. The right lung showed similar but less marked changes. No tuberculosis was found in either lung or in the mediastinal and cervical lymph nodes. The peritoneal cavity contained 7 pints (4 litres) of yellow fluid. The peritoneum and omentum were thickened and studded with white tubercles, chiefly small and discrete but some confluent, and most numerous in the omentum and the visceral peritoneum of the small gut. There were many peritoneal adhesions. The interior of the stomach and intestines appeared normal.

The spleen weighed 52 oz. (1.5 kg.), and on its anterior surface close to the tip was a circular mass 2 in. (5 cm.) in diameter, slightly raised above the surface, consisting of caseous material sharply demarcated by a fibrous capsule. The splenic pulp was soft and the follicular pattern could not be made out. The liver was considerably enlarged and on section was congested and fatty; the gall-bladder and bile ducts were normal. There were several caseous lymph nodes up to ½ in. (1.9 cm.) in diameter grouped around the coeliac axis. The kidneys, suprarenals, and pelvic organs were normal. On splitting the right femur the marrow was seen to be pale pink in colour and soft in consistence, and it extended to the lower end of the bone.

Microscopical Examination.—The omentum contained many tuberculous giant-cell systems, some with caseous centres; occasional tubercle bacilli were found in them. The abdominal lymph nodes contained similar tubercles. In addition, one node contained a large caseous area surrounded by a hyaline fibrous capsule which showed early calcification. There was chronic venous congestion of the liver, which was infiltrated by a moderate number of miliary tubercles consisting of groups of epithelioid cells only, but containing occasional tubercle bacilli. The large mass in the spleen consisted of a structureless granular centre surrounded by a hyaline fibrous capsule. No organisms were found in it. The pulp of the spleen was congested, with hyperplasia of the sinus endothelium and many collections of epithelioid cells. No tubercles were seen in the substance of the lung, but some were present in the pleura. The bone marrow was vascular, few bone trabeculae remaining, and it contained tubercles similar to those in the liver. Haemopoietic cells were reduced in number, most of the cells present being reticulo-endothelial in type, resembling epithelioid rather than primitive myeloid cells.

Case 2

A man aged 67 had suffered from rheumatic fever when 14 years old; otherwise his health had been excellent. Early in 1949 he was admitted to hospital with congestive heart failure and auricular fibrillation. The spleen was enlarged and the liver palpable. He was anaemic (Hb, 46%; red cells, 3,800,000 per c.mm.) and had a leucocytosis of 22,000 per c.mm. (polymorphonuclears 80%). His heart failure and anaemia responded to treatment. By July, 1949, he had become plethoric and a blood count showed: Hb, 130%; red cells, 6,400,000 per c.mm.; white cells, 17,400 per c.mm. Venesection was performed repeatedly.

In February, 1950, he suffered again from congestive heart failure and after treatment was transferred to the Middlesex Hospital for radiotherapy for the polycythaemia. He had lost 14 lb. (6.4 kg.) in weight, looked ill, and had a pyrexia of 98–100° F. (36.7–37.8° C.). The chest was normal on both clinical and radiological examination. The heart was normal apart from auricular fibrillation and a blowing apical systolic murmur. The spleen, firm and slightly tender, was enlarged almost to the umbilicus, and the liver was palpable three fingerbreadths below the costal margin. Ascites was present. A blood count showed: Hb, 103%; red cells, 6,180,000 per c.mm.; white cells, 15,600 per c.mm. (86% polymorphonuclears); reticulocytes, 1.4%; platelets, 600,000 per c.mm. The sternal marrow gave a total nucleated cell count of 49,000 per c.mm. (myeloblasts 0.6%, premyelocytes 3.3%, myelocytes 6%, metamyelocytes 5%, polymorphonuclears 62.3%, lymphocytes 3%, monocytes 7.3%, plasma cells 0.6%). The myeloid/erythroid ratio was 7:1. The erythroid series was within normal limits and there was an increased number of megakaryocytes. He was thought to suffer from a myeloid leukaemic termination of polycythaemia and was given a diagnostic course of x-ray therapy (800 r) to the spleen, without effect upon the leucocytosis, which continued unchanged until his death.

Post-mortem Examination

The heart was enlarged—18 oz. (510 g.)—from hypertrophy of the left ventricle, but was otherwise normal. Both lungs were congested and oedematous, with bilateral pleural effusions. No tuberculous lesions were detected in either lung. The hilar lymph nodes were normal. The peritoneal cavity contained 9 pints (5.1 litres) of blood-stained purulent fluid and there was marked thickening of the peritoneal surfaces, with widespread firm adhesions. The stomach and intestines were normal. The liver weighed 70 oz. (2 kg.) and its capsule was thickened; on section, it was congested and showed diffusely distributed white deposits of miliary size. The spleen weighed 50 oz. (1.4 kg.) and many nodules varying in size from ¼ to ½ in. (0.3 to 1.25 cm.) were found in its substance. Most of the nodules were firm, but some were soft and caseous in their centres. The intervening splenic pulp was greyish red in colour and soft. Both kidneys contained simple cysts. The suprarenals, pancreas, and pelvic organs were normal. The abdominal lymph nodes along the aorta and at the root of the mesentery were enlarged, and on section areas of caseation were seen. A film of the peritoneal fluid stained by Gram's method showed numerous pus cells with profuse Gram-positive cocci and Gram-negative bacilli.

Microscopical sections of the abdominal lymph nodes showed numerous tuberculous giant-cell systems with areas of caseous necrosis containing scanty tubercle bacilli. Sections of the spleen showed considerably larger areas of caseation with extensive fibrosis of some of the lesions, but less granulomatous reaction and no tubercle bacilli. In the liver, miliary tubercles were abundant, with very occasional tubercle bacilli in them. The lungs showed congestion and oedema but no tuberculosis.

Case 3

A man aged 41 complained of lassitude and of pains in the joints for eight days. For five days he had noticed a rash on his skin, initially on the shins but later involving the whole of his body. He was pale and pyrexial—97–99.6° F. (36.1–37.6° C.). There were no abnormal physical signs, apart from a palpable spleen tip on full inspiration and a widespread skin rash. The rash was macular and ecchymotic, the majority of lesions being surmounted by small pustules. The rash did not fade on pressure, was not tender and was most pronounced on the legs. Hess's test was positive.

A blood count on June 19, 1945, showed: Hb, 49% (7.1 g.%); white cells, 2,600 per c.mm. (polymorphonuclears 33%, lymphocytes 63%, monocytes 3%, eosinophils 1%);

platelets, 350,000 per c.mm. A radiograph of the chest was normal. Serial blood counts showed that the anaemia and leucopenia persisted in the range: Hb, 33-49%; red cells, 1,600,000-2,600,000 per c.mm.; and white cells, 1,400-3,700 per c.mm., with an absolute neutropenia and relative lymphocytosis. The sternal marrow gave a total nucleated cell count of 25,000 per c.mm. (polymorphs 11%, metamyelocytes 4%, myelocytes 4%, premyelocytes 2%, myeloblasts 1%, lymphocytes 28%, monocytes 1%, late normoblasts 47%, intermediate normoblasts 2%). The myeloid/erythroid ratio was 0.5:1. A diagnosis was not made; the illness progressed steadily, with increasing fever, until the patient died one month after the onset of his symptoms. During the last week of life the spleen became impalpable, although coincidentally the liver enlarged and became tender on palpation.

Post-mortem Examination

Both pleural spaces contained 5 oz. (140 ml.) of yellow fluid. The lungs were voluminous, both lower lobes being solidified by coagulated oedema fluid, with areas suggesting infection of this jelly-like material. The upper lobes were emphysematous, congested, and oedematous. The hilar glands were enlarged and soft. There were no adhesions or free fluid in the peritoneal cavity. The stomach and intestines were normal. The spleen weighed 28 oz. (795 g.) and was purple in colour. No Malpighian bodies could be identified, but throughout the pulp were many nodules up to $\frac{1}{4}$ in. (0.3 cm.) in diameter, firm, and golden yellow in colour. The liver weighed 72 oz. (2 kg.); the left lobe was represented by fibrous tissue, but the right lobe was enlarged to the iliac fossa. On section there was pronounced mottling, suggesting alternating areas of congestion and fatty change; the gall-bladder and bile ducts were normal. A mass of soft swollen lymph nodes was seen in the upper part of the abdomen around the coeliac axis, individual glands being about $\frac{1}{4}$ in. (1.25 cm.) in diameter. There was a single large calcified gland in the ileo-caecal mesentery. The other abdominal organs were normal. When the sternum was split it was found to contain red marrow; there was red marrow in the neck and upper third of the shaft of the left femur.

Microscopical Examination.—The abdominal lymph nodes, liver, and spleen contained areas of caseous necrosis surrounded by radially arranged cells resembling fibroblasts and by lymphocytes. No giant cells or typical epithelioid cells were seen, but very large numbers of acid-fast bacilli were found. The bone marrow was vascular, but haemopoietic cells were scanty and were surrounded by a loose fibroblastic tissue in which were numerous scattered, minute areas of necrosis. Although tubercle bacilli were absent, the lesions were histologically similar to those seen in the liver, spleen, and lymph nodes.

Case 4

A woman aged 60 complained of a goitre of recent onset and of excessive bruising for some years. Her spleen was palpably enlarged. A blood examination showed: Hb, 96% (13.9 g.); red cells, 5,200,000 per c.mm.; white cells, 7,300 per c.mm. (polymorphs 63%, lymphocytes 30%, monocytes 5%, eosinophils 2%); platelets, 40,000 per c.mm. (two weeks later they numbered 55,000 per c.mm.); bleeding time, $8\frac{1}{2}$ minutes (method of Duke); coagulation time, $4\frac{1}{2}$ minutes (method of Lee and White). Splenectomy was performed without difficulty and the liver appeared normal. Five days later a blood count showed: Hb, 81%; red cells, 4,400,000 per c.mm.; white cells, 18,500 per c.mm. (polymorphs 85%, lymphocytes 9%, monocytes 6%); platelets, 350,000 per c.mm. The patient has remained well and entirely free from purpura since the splenectomy. The spleen was normal in size and weighed $3\frac{1}{2}$ oz. (100 g.). It was firm but showed no abnormality on its cut surface. Microscopically there was some congestion and fibrosis of the pulp. There were occasional typical small tubercles with caseous centres throughout the organ.

Discussion

This type of abdominal tuberculosis probably originated in the para-aortic lymph nodes which had been involved in a lymphatic spread of infection from either a mesenteric or an intrathoracic tuberculous gland. The erosion of a caseous para-aortic node into a visceral branch of the abdominal aorta would disseminate the disease to the liver and spleen and to the intestines. The miliary tubercles in the bone marrow (Cases 1 and 3) cannot be regarded as the result of a blood-borne spread of the disease from the liver because of the absence of similar pulmonary lesions (apart from a few tubercles on the pleura in Case 1), and they remain unexplained.

Cases of this variety of abdominal tuberculosis have been reported under many titles (Winternitz, 1912; Fittipaldi, 1938), the most satisfactory being "atypical abdominal tuberculosis," suggested by Blair and Pagel (1947) in describing four unusual pathological types of tuberculosis of the abdomen. Both sexes may be affected at any age, and, unlike the classical forms of the infection, this atypical disease occurs not infrequently in old people, in whom tuberculosis may easily be disregarded as a cause of hepatosplenomegaly.

The disease has usually begun insidiously, most patients complaining of upper abdominal discomfort and swelling, lassitude, and malaise. Marked loss of weight and fever above 100° F. (37.8° C.) were uncommon. In a few cases a blood disorder has been the presenting feature, and in a minority the disease ran the rapid course of an abdominal tuberculous septicaemia (Ball *et al.*, 1951). Haematemesis has been recorded rarely as an initial symptom (Engelbreth-Holm, 1938; Howells, 1939). The spleen usually reached to, or even beyond, the umbilicus, and was firm, smooth, and often tender, but pain was caused only by infarction. The liver was moderately enlarged, smooth, and slightly tender in most cases. Ascites has been recorded.

When the cause of the hepatosplenomegaly was diagnosed before operation or death it had been suggested by the finding of active extra-abdominal tuberculosis, such as tuberculous lymphadenopathy (Hickling, 1938; Coffee and Lipton, 1943), bone and joint tuberculosis (Konstam, 1949), or active pulmonary disease.

Investigations in this disease have been singularly unhelpful. The Mantoux reaction has been of little assistance (Dietz, 1946). Radiographs of the abdomen may assist diagnosis by showing calcification in the spleen (Shands, 1933; Moorman, 1937), liver and spleen (Konstam, 1949; Astley and Harrison, 1949), or spleen and mesenteric glands (Solomon and Doran, 1939). Calcification in the lesions has been so uncommon that this method of investigation cannot be relied upon always to yield positive information.

There seems to be no certain method of distinguishing atypical abdominal tuberculosis from the many diseases producing a similar clinical appearance, apart from direct inspection of the abdominal contents. Coyon *et al.* (1927) performed splenic puncture and recovered tubercle bacilli from the aspirated material by guinea-pig inoculation. Liver puncture biopsy could perhaps be used with less risk (Graddock and Meredith, 1949).

The haemocytopenias associated with tuberculosis of the spleen have been attributed either to splenic or to bone-marrow tuberculosis. Engelbreth-Holm (1938) suggested that the infected spleen exercised an excessive control upon the emission of blood cells from the bone marrow, and Howells (1939), Dietz (1946), and Meredith *et al.* (1949) reported cases in which a leucopenia was corrected after removal of a tuberculous spleen. Solomon and Doran (1939) and Weiner and Carter (1941) recorded the cure of thrombocytopenic purpura in the same manner. Ball *et al.* (1951) ascribed the leucopenia of their cases of tuberculous septicaemia, and Gouley *et al.* (1949) the thrombocytopenia of their case of purpura and tuberculosis, to the tuberculous foci found in the bone marrow.

The return of the blood cell content to normal after splenectomy may be best explained by assuming hypersplenism, and not marrow tuberculosis, to be the cause of the haemocytopenias; hypersplenism may be excluded only if the blood count fails to respond to splenectomy. Although Ball *et al.* (1951) found marrow aplasia by sternal puncture in one of their cases, we obtained a normal marrow picture in our Case 3 with leucopenia, and the marrow was hyperplastic in the thrombocytopenic case of Gouley *et al.* (1949). The last finding is usual in cases of hypersplenism. Marrow tuberculosis is not always associated with a leucopenia, and in Case 1 there was in fact a leukaemoid reaction without anaemia.

The association of leukaemia and tuberculosis is rare, but a leukaemoid blood reaction may occur in the presence of tuberculosis. If the infection causes splenomegaly the stimulation of true leukaemia may be perfect, the correct diagnosis being obtained only from a biopsy of the liver or spleen. When the tuberculosis is apparently confined to the abdomen its presence may not even be considered. Similarly, patients suffering from hepato-splenic tuberculosis and polycythaemia vera commonly present with no indication of abdominal tuberculosis. The polycythaemia in such cases was attributed to the splenic tuberculosis by Fitzpatrick and Schwartz (1949) when they reviewed the 36 recorded cases. Splenectomy has not been found to reduce the red blood cell count in these patients, and in Guild and Robson's (1950) case both irradiation of the spleen and its subsequent removal increased the severity of the polycythaemia. The evidence available does not confirm a causal relationship between splenic tuberculosis and polycythaemia.

Atypical abdominal tuberculosis has very rarely been treated with the correct diagnosis previously made. Splenectomy was advised by Winternitz (1912) in order to prevent a spread of the infection from the spleen, but it is improbable that the spleen is the most important focus of the disease, and, in fact, the tuberculosis may progress despite this operation (Frank, 1939). Splenectomy may become necessary, however, to relieve abdominal pressure symptoms or to correct a haemocytopenia.

Streptomycin has been used only twice in the treatment of hepatic or hepato-splenic tuberculosis (Guild and Robson, 1950; Melville, 1951). The results obtained were satisfactory, and at present it seems to be the treatment of choice for this condition.

Summary

Four cases of atypical abdominal tuberculosis are reported. Post-mortem examinations were made in three cases, all of which demonstrated tuberculosis of abdominal lymph nodes, liver, and spleen. Two of these cases also had miliary tuberculosis of the bone marrow.

One patient showed a leukaemoid reaction; another appeared to have suffered from polycythaemia; a third, whose illness was rapidly fatal, had a profound neutropenia and anaemia. The last case presented with thrombocytopenia. The relation of these blood disorders to the abdominal tuberculosis is considered.

We wish to thank Dr. G. E. Beaumont, Professor B. W. Windeyer, and Mr. C. J. B. Murray for permission to publish notes of their cases; Professor R. W. Scarff, Professor A. Kekwick, and Dr. T. Parkinson for their advice and criticism; and Miss W. Cory for her secretarial assistance.

X-RAY APPEARANCES IN ASTHMA

A STUDY OF 200 CASES

BY

HAROLD ROYLE, M.B., B.S.

(From the Allergy Clinic, County Hospital, York)

The object of this investigation was to review the x-ray appearances in a series of patients suffering from asthma, together with the clinical findings in the same subjects, in order to find out if x-ray appearances could be correlated with clinical types, and to see in what proportion of cases complications occur.

Previous reviews of radiological findings in asthma—for example, Lapage (1922), Manges and Hawley (1927), Bray (1930)—are remarkable for the wide variety of terms used and for the comparatively few films which were regarded as normal. Little effort was apparently made to recognize emphysema, which we know clinically to be such an important and common complication, and segmental collapse was either not seen or not recognized at all.

Present Series

This series consists of 200 cases of bronchial asthma investigated at an allergy clinic, unselected in any way except that they were divided into two groups, the first consisting of 100 children aged from 14 months to 12 years, the second of 100 adults from 13 to 65 years. Such a division was found convenient, not because I consider that there is any fundamental difference between asthma in childhood and asthma in adult life, but because it is easier to compare films of similar-sized chests, and also because obviously the average duration of the disease will be longer in the older age group.

Table I shows the distribution between the sexes, the family history of allergy, and the average duration of the disease. There is little need to comment on these figures.

TABLE I.—Sex Incidence, Family History, and Average Duration of Disease

	Children 1-12 Years	Adults 13-65 Years
Total No. of cases	100	100
Males	66	50
Females	34	50
Positive family history of allergy	66	58
Negative	27	26
Family history doubtful or not available	7	16
Average duration of disease	3 yrs. 10 mths.	11 yrs. 10 mths.

which show the usual preponderance of males over females among the children, and the large proportion with a positive family history of allergy (including asthma, hay-fever, chronic urticaria or dermatoses of allergic type, and migraine). They differ in no important respect from the many other similar series which have been published.

Aetiology

With regard to aetiology we find ourselves on very controversial ground in the present state of our knowledge. The classification adopted is one which is thought likely to be acceptable to a majority of students of asthma. While it is true that often more than one aetiological factor is operative, most cases fall into the broad groups set out in Table II: (a) "extrinsic" allergy—that is, hypersensitivity

TABLE II.—Aetiology

	Children	Adults
(a) Extrinsic allergy	42	38
(b) Intrinsic allergy	15	17
(c) Combined	40	31
(d) Cause not definitely assigned	3	14

to specific inhaled or ingested allergens, giving rise to excessive antigen-antibody reactions; (b) "intrinsic" allergy, or hypersensitivity to invading micro-organisms or their products in the respiratory tract (this type is sometimes called infective asthma); (c) a combination of extrinsic and intrinsic allergy; (d) a group of cases in which an aetiological diagnosis was not made. Psychogenic factors and peripheral irritation are recognized as being important, but are regarded as being subsidiary or reinforcing. The relationship to endocrine activity is still too obscure to be useful from a classification point of view.

The diagnosis of infective asthma was made on clinical grounds: history, physical examination, pus in sputum or nasal discharge; and specialized rhinological examination. Laboratory help in the form of sputum examinations, blood counts, and sedimentation rates was sought in those cases where it was considered necessary. No single test was found to be reliable enough to make a diagnosis of bacterial allergy without support. The sedimentation rate, though increased when infection is active, gives no help in those cases of asthma caused by infrequent acute respiratory infections, where investigation is carried out in the free interval. Blood eosinophil counts were very variable, sometimes rising to 25% or more, and did not seem to bear any direct relation to the type of case under investigation.

Sinus Radiographs

Sinus radiographs showed, rather unexpectedly, a higher proportion of abnormalities in the children (62%) than in the adults (54%) (Table III). These figures compare closely

TABLE III.—Abnormalities Shown by Sinus Radiography

	Children	Adults
Minor changes (slight mucosal thickening, etc.)	19	18
Marked changes (complete opacity, gross mucosal thickening, etc.)	43	36
No abnormality	38	46

with those of Unger (1945), who analyses nine reports of the incidence of sinus disease in asthma, giving an average of 60.4%, with a 26-82% variation.

It appears to be true that many "normal"—that is, symptom-free—individuals show opacities or mucosal thickening on sinus radiographs; Kern and Schenck (1929) found as many as 72% in 50 non-asthmatic controls. If we are to accept the work of Grove and Cooke (1933), these changes, which only in acute exacerbations become suppurative, are always caused by an infection which, in certain subjects, could at least theoretically lead to bacterial sensitization with resultant asthma. There is still, however, considerable lack of uniformity of opinion on the significance of these findings, and until there is more certainty I have tended to adopt a conservative attitude, and an abnormal sinus radio-

graph without other clinical evidence of infection has not been deemed sufficient to place the case in the infective groups.

Chest Radiographs

From the point of view of radiological appearances the cases seemed to fall naturally into the groups shown in Tables IV and V. A large number appeared to be within normal limits; others were normal apart from varying degrees of emphysema; another group, including some of the emphysematous ones, had markedly increased hilar shadows, with or without calcification; while a much smaller group had other important abnormalities.

Minor abnormalities, such as congenital malformations of the ribs, small diaphragmatic adhesions, small calcified

TABLE IV.—Chest Radiographs in 100 Children

	No. of Cases	Infective	Non-infective	Average Duration
No abnormality	57	24	33	2 yrs. 11 mths.
Emphysema only	22	16	6	5 yrs. 9 mths.
Emphysema plus increased hilar shadows	6	5	1	
Increased hilar shadows	11	7	4	
Other important abnormality (4 cases):				
Segmental collapse	4	3	1	

TABLE V.—Chest Radiographs in 100 Adults

	No. of Cases	Infective	Non-infective	Average Duration
No abnormality	30	9	21	9 yrs. 6 mths.
Emphysema only	35	14	21	12 yrs. 1 mth.
Emphysema plus increased hilar shadows	11	8	3	
Increased hilar shadows	14	10	4	
Other important abnormality (10 cases):				
Segmental collapse	4	2	2	
Pulmonary tuberculosis	3	3	0	
Miscellaneous	3	3	0	

lesions in the lung fields, and so on, were not taken into account, nor were the enlarged heart shadows of the occasional adult with coincidental hypertension.

For the purpose of comparing the x-ray findings with clinical types it was found most convenient to divide the latter quite simply into infective and non-infective cases. The infective group consisted of those with "intrinsic" allergy (b) and the "combined" type (c) in Table II; the non-infective comprised the other two types, (a) and (d) in Table II.

Emphysema

It is important, from the point of view of prognosis, to distinguish between irreversible chronic "hypertrophic" pulmonary emphysema and pulmonary distension due to an asthmatic attack. In order to do this it may be necessary to repeat the physical and x-ray examination, and the measurement of vital capacity, at a time when the patient is "at his best"; this has been done in some cases in the series under review. Considerable help in the diagnosis can be obtained by taking films in full inspiration and full expiration and comparing the difference in translucency, density of the broncho-vascular markings, height of the diaphragm, etc., in the two films. Comparison between a film taken in expiration with that of a normal control of similar age and build has also been of assistance in some cases. In spite of these devices, however, there is probably a margin of error, especially in the case of the children, where scope for examination is of necessity somewhat limited.

Tables IV and V show that emphysema, as we would expect, was found in a greater number of adults than children (46 to 28). In both children and adults the average

FIG. 1.

FIG. 2.

FIG. 1.—Segmental collapse, middle lobe, in girl aged 11. FIG. 2.—Segmental collapse, middle lobe, in man aged 36.

duration of the disease was longer in those with emphysema. In the adults the distribution of emphysema between infective and non-infective cases was about equal (22 to 24), but in the children the infective type largely predominated (21 to 7). This might be interpreted as indicating either that infective asthma is more severe in children or that the chronic cough, which many of the infective cases have, produces that added strain on the alveolar walls which determines the onset of emphysema. In the case of adults, the element of chronicity alone seems to be of importance.

Increased Hilar Shadows

It is assumed that, for all practical purposes, these indicate enlarged tracheo-bronchial glands, which again argues past or present lung infection. Some of these were undoubtedly due to a primary tuberculous infection in early childhood, others to acute or chronic non-tuberculous bronchial or pulmonary infection. It is therefore not surprising to find that in this group the infective cases largely predominate (30 infective to 12 non-infective in the whole series).

Bronchiectasis

This has not been taken into account here. Without doing routine bronchograms it would obviously be impossible to say what number had developed this complication, and bronchograms have been done in only a small number of cases. Of the whole 200, including those with phthisis, only nine had any haemoptysis, and this was usually slight, while clubbing of the fingers was seen in only two. Bullen (1933) found bronchiectasis in 7.75% of asthmatics, and Chapman and Hoskins (1941) state that when it occurs it is usually of the cylindrical type. Only one of our bronchograms showed definite saccular bronchiectasis, and my impression is that permanent bronchiectasis of clinical significance is not a common complication of asthma.

"Thymic" Asthma

Pressure on the trachea by an enlarged thymus is sometimes given as a cause of asthma—like dyspnoea in infants and young children. A lookout was kept for any radiological evidence of enlarged thymus, but it did not appear. It must be uncommon, and hardly a force to be reckoned with from the point of view of differential diagnosis.

Segmental Collapse

This was seen in eight cases (four children and four adults). Among the children it affected the middle lobe in three cases and the left lower lobe in one case. The latter took over a month to re-expand, whereas in

the others re-expansion was rapid. In one case there was complete disappearance of the typical wedge-shaped shadow in a film taken 24 hours later (see Fig. 1). Of the four adults with segmental collapse the middle lobe was affected in three cases, and the lower part of the left upper lobe in the other. In all cases re-expansion was rapid (see Fig. 2).

It should be emphasized that all these patients were investigated as out-patients, and that none was acutely ill at the time. Except for the child with left lower lobe collapse, I do not think that it would have been possible to diagnose the condition without radiographs. The severity of the patient's asthma seemed to bear no relation to the presence of collapse. One man, who had been gravely ill with acute asthma as an in-patient, had a clear x-ray film when in hospital. When referred for investigation 10 days later as an out-patient, much improved, another x-ray film showed an area of collapse, which completely disappeared within the next week, without any noticeable change in his physical condition.

It seems probable that collapse, due presumably to the blocking of a smaller or larger tube by a mucous plug, is commoner in asthma than is generally realized, though all degrees of it, up to massive collapse of a whole lung, have been described by various writers—for example, Clarke (1930), Maxwell (1937), Friedman and Molony (1939).

Pulmonary Tuberculosis

There has been much speculation in the past about a possible relationship between pulmonary tuberculosis and asthma, but most of the available evidence suggests that the former occurs no more frequently in asthmatics than in the population as a whole. In the series under review no cases of active pulmonary tuberculosis were found among the children, but three adults, aged 29, 35, and 65 years, had the disease. All of these were asthmatics of long standing; two had positive family histories of allergy, and all had tubercle bacilli in the sputa. The incidence of 1.5% of phthisis in this series is probably higher than that in the total population, but the numbers involved are too small for any conclusion to be drawn from this.

Miscellaneous Abnormalities

Three cases come under this heading. The first was a woman of 60, with a lifelong history of asthma, whose radiograph showed part of her stomach to be above the

FIG. 3.

FIG. 4.

FIG. 3.—Thoracic stomach. Woman aged 60. Lateral film. FIG. 4.—Dense opacity, left lower lobe. One of several opacities recurring in different situations.

diaphragm. There was an ulcer on this portion, from which she later had a large haematemesis. This condition had, of course, no relation to her asthma, but the case serves to illustrate how important coincidental conditions sometimes come to light in the course of a routine investigation (see Fig. 3).

The other two cases, both young adults with incessant asthma since infancy, showed recurrent evanescent shadows in different situations on their chest radiographs during a follow-up period of over four years. One patient subsequently twice developed pulmonary abscesses, which she spontaneously evacuated, and material sucked from the infected area through a bronchoscope grew a *Streptococcus viridans*. The other patient also at one time developed a small abscess cavity with a fluid level, which quickly disappeared spontaneously. In neither case did the blood eosinophils ever exceed 6% (see Fig. 4).

Transitory opacities seen in the chest radiographs of asthmatics, such as occurred in the last two cases, have been described by many authors—for example, Peshkin (1927) and Sédillot (1934). There has been considerable speculation about their nature, particularly whether they are caused by localized areas of infection or by eosinophilic infiltration. The character of these two cases suggests that infection is the cause in some of them.

Summary and Conclusions

A review of the radiological findings in 200 cases of asthma, 100 children and 100 adults, is presented, and an attempt made to correlate the x-ray appearances with clinical findings. The series consists of typical cases of asthma, seen as out-patients only.

Sinus radiographs show changes in over half the cases, there being a higher proportion with marked abnormality in the children than in the adults.

Chest radiographs, disregarding minor abnormalities, fall into five groups: normal, emphysema, emphysema and increased hilar shadows, increased hilar shadows, and other important abnormality. The last group includes cases of pulmonary tuberculosis, segmental collapse, and recurrent transient shadows believed to be due to localized areas of infection.

In attempting to distinguish between irreversible emphysema and pulmonary distension due to the bronchiolar obstruction of asthma, the value of radiographs taken in full inspiration and full expiration, and of comparing one taken in expiration with a normal control, is stressed.

Emphysema is the commonest complication, and is judged to be present in 28 children and 46 adults. The evidence suggests that both chronicity and infection are important factors in its development.

Enlarged hilar shadows are present in a higher proportion of the infective than of the non-infective cases. Segmental collapse, with subsequent satisfactory re-expansion, is present in 4%, and is seen in both infective and non-infective types. Active pulmonary tuberculosis is found in 1.5%.

In conclusion it should be pointed out that the chest radiograph in uncomplicated asthma is normal, but that a great deal of help can be obtained from radiography in the diagnosis of complications, in the elucidation of the aetiology, and in the discovery of coincidental conditions.

I should like to express my thanks to Drs. C. N. Pulvertaft and R. A. Ashwin, consultant radiologists to the County and City General Hospitals, York, whose co-operation and assistance with the radiological diagnosis have made this investigation possible.

THE TREATMENT OF RECENT TRANSCERVICAL FRACTURES OF FEMUR

BY

D. O. WILLIAMS, M.B., F.R.C.S.

Senior Surgical Registrar, Southlands Hospital,
Shoreham, Sussex

AND

E. K. McLEAN, M.B., F.R.C.S.E.D.

Surgeon Superintendent, Southlands Hospital,
Shoreham, Sussex

Much has been written on this subject during the past 20 years, and our only excuse for adding to the literature is that we have evolved a simple method of treating these injuries, the results of which seem to compare favourably with those of any other method so far described.

It is now generally agreed that the treatment of choice in transcervical fractures of the femur, particularly those of the adduction type, is some form of nailing operation, with or without a bone graft according to the nature and age of the fracture; and our treatment is based on the internal fixation operation originally described by Smith-Petersen *et al.* in 1931. During the past four years rather more than 100 such operations have been carried out, and we wish to describe the management and the results in a consecutive series of 100 cases in which the end-result is clear. The number of patients involved was 98, two of them having the second hip nailed a few months after the first. The great majority of them were women, the injury being much less common in men.

Selection and Management of Cases

Abduction fractures with impaction are excluded from this series, it being unnecessary to operate on most of them. Apart from these, all the cases admitted with adduction fractures of the femoral neck have been included, and were subjected to operation unless they were moribund or were suffering from advanced senile mental changes. Indeed, several cases from a neighbouring mental hospital have been successfully treated.

Unlike Bankart (1942), who advocated that few patients over the age of 80 should be operated upon, we have not made age alone a bar to operation. The average age in this series was 73, and the range extended from 44 to 93, 60% of them being in the age group 71-85.

On admission all patients are subjected to a full clinical examination and radiographs are taken of the injured hip to determine the nature of the fracture. The patient is then put to bed and a simple form of skin traction is applied to the injured leg by means of extension strapping applied below the knee. The usual weight employed is 9 lb. (4 kg.), which is connected to the strapping by means of a cord passing over a pulley attached to the lower bed-rail. This simple form of traction does not immobilize the

fracture, but it has the merit of preventing, or correcting, any gross shortening. It also steadies the limb, thus relieving the patient of a considerable amount of pain.

Should the general examination reveal the presence of moist sounds at the lung bases, penicillin is given in the form of its procaine salt, 300,000 units daily; and in all cases breathing exercises are begun under the direction of a physiotherapist. A simple explanation is also given of the patient's post-operative management, and foot drill is initiated. In most cases no other pre-operative measures are carried out, but should a patient be suffering from diabetes mellitus this is stabilized as rapidly as possible. None of the resuscitative measures described by some surgeons (Harmon, 1945), such as blood transfusion, have been found to be necessary. As soon as a suitable opportunity occurs the patient is operated upon, and this is usually carried out within a few days of the injury.

The Operation

Here again simplicity has been our keynote, and all direction-finding aids have been discarded except one—namely, the hinged gauge (London Splint Co.). All patients have been given a general anaesthetic, usually thiopentone, gas-oxygen, and "trilene," with D-tubocurarine or similar drug, and the operation is nearly always completed well within an hour.

A slightly modified fracture table is employed, a padded wooden platform being fitted in place of the usual small sacral rest. Beneath the platform is a slot into which cassettes can be inserted without disturbing the position of the patient.

The patient is placed upon the table and enough traction put on the uninjured limb to steady the pelvis. The injured limb is then manipulated by hand into a position of abduction and internal rotation and enough traction applied to render the limb just taut. In nearly all cases these simple manoeuvres are sufficient to ensure full and accurate reduction of the fracture.

As Van Gorder (1948) and others have already mentioned, a bony spike attached to the inferior border of the femoral head may make accurate reduction difficult, and it may be shown that further manipulation is necessary after the initial x-ray films are developed.

Two portable x-ray units are then placed in position and the hinged gauge is attached to the front of the hip with strapping in such a position that the hinge lies just below the anterior-superior iliac spine; one limb lies in the groin crease and the other lies in the line of the femoral shaft. After the first films are developed, the accuracy of the reduction is checked, and from the superimposed image of the gauge in the antero-posterior film two points can be marked on the skin with methylene blue which, when joined, will show the correct line for the nail in the horizontal plane. The correct line for the nail in the vertical plane is taken as being parallel with the floor, with, if anything, a slight posterior tilt.

It has been our aim to insert the nail at a slightly more oblique angle to the shaft than the long axis of the femoral neck, as advocated by Bankart (1942), thus converting shearing forces at the fracture site, especially in those cases corresponding to Pauwel's (1935) group 3, to impacting forces. We also try to complete the operation with the nail lying slightly behind and below the long axis of the neck, and with its tip coming to rest just beneath the articular surface of the head. With the nail so placed, there is much less danger that it will cut out if the femoral head undergoes avascular necrosis or if the capital fragment is very small.

With these aims in mind the operation is proceeded with in the usual way, the guide-wire being inserted well into the head fragment to prevent rotation while the nail is being hammered in. We have no objection to the guide-wire perforating the articular cartilage of the head, but do not make a point of pushing it right through into the pelvis, thus completely transfixing the head, as described by Bankart. The guide-wire is of known length, and the correct size of

nail can be determined by measuring the length of guide-wire protruding from the lateral cortex of the femur. The nail is hammered in over the wire, without the preliminary use of a starter. The wire is withdrawn, traction on the limb is slackened, and the fragments are impacted with a few blows from the mallet.

The wound is then closed, no additional measures, such as the insertion of cross-pins, being taken to prevent the nail from sliding out during convalescence. There are two reasons for omitting this step. The first is that if the nail should become loose enough to allow lateral extrusion the anchoring cross-pin will probably loosen also. The second is that complete prevention of lateral sliding is apt to cause slight separation of the bony fragments due to the bony absorption that occurs about any fracture during the early stages of healing, and therefore gives rise to delayed union or non-union.

Post-operative Care

Various methods of restricting external rotation of the injured limb after operation have been tried and discarded. As a routine measure we now use the abduction frame designed by McLean (1949). This frame prevents external rotation and adduction of the limb while permitting flexion and extension of the knee- and hip-joints. It also acts as a bed-cradle, thus relieving the legs of the weight of the bedclothes.

The day after operation active exercises under the direction of a physiotherapist are begun, all movements of the hip, knee, and ankle being permitted except external rotation and adduction of the hip-joint.

At the end of one month a radiograph of the injured hip is taken, and if the position of the nail and of the bony fragments has been maintained the patient is allowed up daily for non-weight-bearing exercises on crutches. Further x-ray films are taken at intervals of a month, and, provided that there is radiological evidence of bony union, graduated weight-bearing exercises are begun at the end of three months. If union has not occurred, or its degree is doubtful, weight-bearing is postponed until it is definitely present, and this may mean a delay of six months or more in some cases.

Provided home conditions are satisfactory and the general condition of the patients is good, they are discharged from hospital when they have learnt to manage crutches. Most of our cases, however, have remained in hospital for the full three months, principally because they lived alone.

Results of Treatment

In view of the fact that the nailing operation has been carried out in every case unless it was obvious that the patient was moribund on admission, we believe our results compare favourably with most of those published to date. A few surgeons have achieved a higher percentage of union, but they have usually been on a smaller series of cases and a more careful selection has been made, thus lessening the risk of failure.

In our series of 100 operations, union has been achieved in 75, with one death attributable to the operation. This death occurred in a woman, aged 85, 24 hours after operation. Altogether nine patients died while under treatment, but in eight death did not occur until several weeks or months after operation, and in none of them could the cause be related to the operation. The full results are summarized below.

No. of patients	98
No. of operations	100 (bilateral in two patients, aged 66 and 78)
Average age	73 (range 44-93)
No. united	75
No. ununited but ambulant	10 (7 with and 3 without callipers)
No. of nails removed	4 (1 had united)
Incidence of wound sepsis	Nil
Deaths while under treatment	9
Causes of death:	
1	operative shock, aged 85
1	cerebral arteriosclerosis (senility), aged 81
2	myocardial degeneration, aged 80
1	pulmonary embolism, aged 74
1	acute gastro-enteritis and cardiac failure, aged 79
1	coronary thrombosis, aged 75
2	hypostatic pneumonia, aged 74 and 76.

Summary

A simple method of treating adduction fractures, and abduction fractures which have disimpacted, of the femoral neck is described. The results appear to be satisfactory according to modern standards. Bone grafting was not carried out in any case.

In those cases in which the nailing operation failed, further surgical intervention was not undertaken because of the age of the patients and their general condition.

We are indebted to Sister Pinfield, the sister of the ward in which most of these patients were treated; to our anaesthetist, Dr. R. E. Gibson; and to Miss Savin and her all-too-small band of physiotherapists for any success we may have achieved in the management of this series of fractures.

ADDENDUM.—Since this paper was written one more case must be listed as a failure. Thus the percentage of successful cases in this series is 74.

THE KAHN TUBE TEST WITH DROPPING-PIPETTES

BY

OMAR KHAIRAT, Ph.D., M.B., D.T.M.&H.

Professor of Bacteriology, Farouk University, Alexandria, Egypt

In recent years many laboratories have abandoned the Wassermann test and substituted the Kahn standard tube flocculation test as being superior to complement-fixation methods. The belief that the Kahn test gives more false positive results than the Wassermann has been seriously challenged by Berger and Sutherland (1944). But though the Kahn method is relatively simple, in performance it is exacting, especially in the measurement of small volumes of antigen in graduated pipettes. This disadvantage can be largely overcome, and the test set up more rapidly, by the use of pipettes standardized to deliver drops of known volume. Such pipettes have already been advocated in other serological tests for the diagnosis of syphilis—for example, in the Wassermann reaction (Donald, 1916), the sigma reaction (Dreyer and Ward, 1921), and in slide flocculation tests (Mazzini, 1942; Gradwohl, 1943; Harris et al., 1948).

As regards the Kahn test, the volumes of reagents used are economical and the smallest practicable for volumetric work in test-tubes. Osmond (1940) used a dropping-pipette to deliver the standard 0.0125 ml. of antigen suspension. He recommended a pipette with a tip diameter equivalent to No. 54 on the Morse scale (1.397 mm., or 0.055 in.).

Two pipettes are described below—one for the delivery of 0.0125-ml. volumes of antigen, the other for 0.15-ml. volumes of the patient's serum.

Dropping-pipette for Antigen

30-cm. lengths of 7-mm. soft glass tubing are drawn to make two pipettes. The tip diameter is found by thrusting the capillary portion into the No. 55 Morse gauge hole

(1.321 mm.) of a Starrett plate and cutting the tube at the point where it jams in the hole. When cut the capillary portion should be about 6 cm. long, with sides nearly parallel for the last 4 cm. The external diameter of the tip, which should be 1.30 mm. (0.051 in.), is checked by a micrometer screw gauge, making two measurements at right-angles to one another. It is useful at this stage to mark the capillary shaft with waterproof ink exactly 1 cm. from the tip, so that after cleaning, etc., pipettes with broken tips may be readily recognized and discarded.

The correct diameter (1.30 mm.) was arrived at as follows. A pipette was calibrated with mercury to contain 1 ml., and the weight of 1 ml. of antigen suspension was found to be 0.91 g. Weighed 0.91-g. amounts of the antigen suspensions were then drawn into dropping-pipettes of different tip diameter to determine which delivered 80 drops to the ml.—that is, 0.0125 ml. per drop. (A 1.397-mm. pipette (Osmond, 1940) was found to deliver 77 drops to the ml.)

This volume is delivered in one drop when the rate of dropping is one per second from a vertically held pipette. But even with care in maintaining an even rate of dropping there is some variation in the size of the drop. It was not possible, however, to minimize the error by delivering the same volume of liquid in a number of smaller drops. Thus to deliver two drops of half the required volume (0.00625 ml.) a tip diameter of 0.62 mm. was necessary, and capillary shafts of this size are too fragile for routine use.

Compared with 0.1-ml. graduated pipettes, marked to deliver 0.0125-ml. volumes, the dropping-pipette is much quicker and easier to use. In a two-tube test, one receiving one drop (0.0125-ml.) and the other two drops (0.025 ml.), it took about four minutes to dispense antigen suspension for 100 tests. With graduated pipettes the same operation took 22 minutes. The dropping-pipette technique is readily acquired by the laboratory technician, whereas the use of graduated pipettes demands more experience and entails much more eye strain.

Dropping-pipette for Patient's Serum

The Kahn standard test requires the delivery of 0.15-ml. volumes of serum. The weight of 1 ml. of a pool of five inactivated human sera proved to be 1.02 g. Of this pool 0.918-g. amounts (0.9 ml.—that is, six 0.15-ml. drops) were tested in pipettes of different tip diameters, with the following results:

Tip Diameter (mm.)	No. of Drops in	
	0.9 ml.	0.15 ml.
2.8	18	3
5.0	12	2
9.3	6	1

Only the results with pipettes delivering simple fractions of 0.15 ml. are cited above. The 2.8-mm. diameter was selected because in practice the variation in volume is less when the 0.15 ml. is delivered in three drops than in two or one.

With this 2.8-mm. pipette, delivering 0.15 ml. of serum in three drops (0.05 ml. of serum per drop) at the rate of one drop per second, 100 sera could be dispensed, each in three 0.15-ml. volumes and with a triple rinse of the pipette in saline for each serum, in 33 minutes. With a graduated 1-ml. pipette, similarly rinsed for each serum, the same operation took 45 minutes.

The Kahn Test with Dropping-pipettes

Apart from the saving of time and labour in the performance of the test, and the ease with which accurate dropping-pipettes can be constructed by a competent laboratory technician, the dropping-pipette technique permits a modification that is useful, especially when the test is done in hot climates. In the standard test the antigen suspension is dispensed first, and when large numbers of sera are to be tested there is a real risk of evaporation of the smallest dose (0.0125 ml.) of liquid. Serum is added to antigen, and not vice versa, presumably because the antigen pipette might

become contaminated with serum left on the upper part of the tube when graduated pipettes are used. With dropping-pipettes, on the other hand, there is no chance of such cross-contamination, and the bulkier serum volume, which is proportionately less susceptible to evaporation, can be dispensed first. It is, indeed, convenient to dispense the serum while the antigen suspension is "ripening."

There seems to be no good reason why this change in the order of adding reagents should not be made. In order to make sure that nothing goes wrong if Kahn's recommendations in this respect are not adhered to, 500 sera were tested both ways, 100 on each occasion, using the same bottle of antigen each time. The results, in which 60 of the sera were positive, agreed in every instance.

Another economy can be achieved by omitting the first of the three tubes used in the Kahn standard test (Osmond, 1940; Pantton and Marrack, 1947). This tube contains the largest volume of antigen suspension (0.05 ml.), and its omission not only saves time and labour but results in a very real saving of antigen. The only advantage of this tube seems to be that its floccules, when present, are usually the most easily visible with the naked eye when the two other tubes have to be read with the aid of a magnifying glass. There is no great loss when that tube is omitted, because a magnifying lens has to be used in any case. The most useful magnifying glass for detecting small floccules is one that shows them in sharp focus when the lens mount is applied in direct contact with the tube. The Bausch and Lomb $\times 7$ achromatic focusing magnifier (for photomicrography) satisfies this condition. A microscope eyepiece can be used if the top lens is removed and the observer's eye applied to the lower end. The Bausch and Lomb $\times 5$ Huygenian eyepiece is satisfactory, because the Kahn tube can be held in contact with the end of the eyepiece tube, from which the top lens has been removed. Not all makes of eyepieces are suitable.

Summary and Conclusions

The performance of the Kahn standard test is greatly facilitated by the substitution of dropping-pipettes for graduated pipettes. Dropping-pipettes are easy to make and simple to use without eye strain.

A dropping-pipette with an external tip diameter of 1.3 mm. delivers the required standard 0.0125-ml. volume of Kahn antigen suspension when the rate of delivery is one drop per second. In routine tests antigen is dispensed in about one-fifth the time needed with graduated pipettes.

A dropping-pipette with an external tip diameter of 2.8 mm. delivers the required standard of 0.15-ml. volume of serum in three drops when the rate of delivery is one drop per second. It can be readily rinsed in saline for each serum. Compared with graduated pipettes, its use in dispensing serum makes routine tests about 30% quicker.

In the Kahn standard test, sera are dispensed after the antigen, and the small 0.0125-ml. volume of antigen may partly evaporate before serum is added. With the dropping technique the bulkier volume of serum, from which evaporation is proportionately less, may be dispensed first.

Medical Memoranda

Hour-glass Bladder

The name hour-glass bladder seems familiar, but it is not mentioned in several standard textbooks consulted. Perhaps the apparent familiarity of the title is due to memories of hour-glass stomach. However, the following case seems worthy of record as an hour-glass bladder.

CASE REPORT

A spray painter aged 33 was seen at the West London Hospital on March 21, 1946. He had had cystitis, with difficulty of micturition, in 1942 and 1945, when cystoscopy, sulphanilamide, and prostatic massage figured in the treatment. He now again had had difficulty of micturition for nine months, with burning during the act, and slightly increased frequency (D/N=2-4 hours/0-1), but no haematuria. He also had a feeling that he was not emptying the bladder properly, and had occasionally noticed swelling of the abdomen during the past nine months, with some suprapubic tenderness, and nine months previously had had acute retention.

There was no venereal history or any evidence of stricture or enlarged prostate. The urine contained pus in fair amount, a few red cells, and many coliform bacilli. *Proteus vulgaris* was grown.

Plain x-ray films on March 28 and April 8 showed no stone shadow, but apparently a big bladder shadow that filled the pelvis. Intravenous urography on the latter date, while showing good bilateral renal excretion shadows in five minutes without renal or ureteric dilatation, also showed a big bladder shadow, filling the pelvis, even after micturition.

On April 4 cystoscopy revealed a bladder capacity of 3 pints (1.7 litres) and a well-marked narrow ridge, projecting forwards from the posterior wall, with the ureteric orifices situated laterally on the ridge. The blood urea was then 72 mg. per 100 ml. On April 11 the bladder was still up to the umbilicus after the withdrawal of 2 pints (1.1 litres) of residual urine. A $\frac{1}{2}$ English metal bougie was passed. The urine urea was 0.98%.

On admittance on April 12 the bladder, over which there was no tenderness, was found distended only half-way to the navel. Dr. Redvers Ironside found no organic signs referable to the nervous system or any clinical evidence of associated congenital abnormality.

On April 23, after a period of catheter drainage and bladder lavage, cystoscopy again showed a free interureteric bar, and cystotomy a large bladder with thickened and reddened mucosa lying convexly inwards in flabby folds.

A transverse fold, attached posteriorly, free anteriorly, and projecting forwards like a shelf, lay loosely across the bladder, with the right ureteric orifice identified and probed on it, and a very deep capacious proximal recess, bigger than a closed fist, and seemingly bigger than the distal division of the bladder.

The fleshy fold was held up and, $\frac{1}{2}$ in. (1.3 cm.) to the left of the right ureteric orifice, was cut antero-posteriorly in the middle line for about 2 in. (5 cm.), the cut not reaching to the bottom of the fold, yet entering a cavity—not the rectum, but presumably the recto-vesical interval.

The proximal mucosa was sewn to the distal mucosa by a continuous suture on the right and left of the V-shaped gap thus formed, the temptation to cut away the resulting triangular flaps being resisted because of the ureteric orifices on the free margin of the fold. The bladder and space of Retzius were drained by plain tubes.

Looking again at the intravenous urography films one detects, in the 30-minute film, some evidence of this curious division of the bladder cavity into two compartments.

On July 1 the blood urea was down to 48 mg. per 100 ml., and the residual urine to 9 oz. (255 ml.), the catheter urine showing a deposit of epithelial cells, a few leucocytes and red cells, triple phosphate crystals, and numerous Gram-

negative coliform bacilli, growing as *Proteus vulgaris*. On July 8 the residual urine, thick and purulent, was down to only 6½ oz. (185 ml.), while the deposit from the mid-stream urine contained a few pus cells and a few streptococci, growing poorly as non-haemolytic streptococci. The patient has not been subsequently seen, and cannot be traced.

As stated, the recess proximal to this extraordinary transverse fold, which is obviously congenital, and whose origin may be left to embryologists, seemed larger than the distal recess; and it appeared as if a collection of urine in the upper pocket might distend the fold downwards and so obstruct the internal urethral meatus. The median division of this fold would, it might be supposed, prevent this by allowing urine to flow freely from the upper to the lower pocket. That this reasoning is correct is suggested by the course of the case, mere median division of the fold being followed by a fall in the residual urine from 60 to 6½ oz. (1,704 to 185 ml.).

It would be interesting to know if others have met with similar cases.

ALEX. E. ROCHE, M.D., M.Ch., F.R.C.S.

Blindness in Southern Nigeria

What are the causes of blindness in Southern Nigeria? Does blindness in this part of tropical Africa result mainly from tropical diseases, epidemic or endemic? As there were no reliable answers to these questions and as this subject is of considerable importance, an attempt was made to investigate and to record the immediate and remote causes of all cases of blindness seen at the Lagos Eye Clinic.

Harold Ridley (1945) has described an area in the Gold Coast where a considerable number of the inhabitants are blind from onchocerciasis, which is endemic in that district. No condition comparable to this has as yet been discovered in Nigeria. Trachoma is widespread and entropion from contraction of the lids has been reported to be very common in the Northern Territories of the Gold Coast and Northern Nigeria (Dr. Cave and Dr. Branch, personal communications). It was seen less often in cases from Southern Nigeria.

It has been said that a large proportion of the blindness in Nigeria is due to epidemics of smallpox. Occasionally, in cases of leucoma, the patient has stated that smallpox was the direct cause of the condition, but accurate information about the real number so affected is lacking, and there are no grounds for such a dogmatic statement. Tropical diseases undoubtedly increase the liability to blindness by lowering tissue resistance to infective processes, but it is not possible to assess the effects of malaria, helminthic disease, etc., which are commonly found coincidentally with eye disease in Southern Nigeria.

RESULTS OF INVESTIGATION

The Lagos Eye Clinic deals with 7,000 new cases yearly and 20,000 attendances. From 1946 to 1949, inclusive, all cases of blindness attending the clinic were examined and the records kept. The standard of blindness adopted was visual acuity less than 3/60 Snellen. In a large number of cases it was not possible to do more than make a diagnosis of the condition present at the time of the examination. There were, for example, 29 persons totally blind with staphyloma, leucoma, or phthisis bulbi. When these patients were led into the clinic it was apparent that treatment could not improve their condition. In such cases it is not always advisable to ask questions about the origin of the condition. Almost all the cases recorded were from Southern Nigeria, being referred from district hospitals or coming of their own volition.

Total Blindness.—The accompanying Table shows that the commonest causes are cataract, glaucoma, and optic atrophy in that order of frequency. To the figure for cataract might be added the 11 cases blind from the operation for couching. So far as I am aware the fact that couching for cataract is being done in Nigeria has not hitherto been reported. It is probable that as the more orthodox

Table of Blindness

Causes of Blindness	Blind in Both Eyes	Blind in One Eye
Leucoma, phthisis, staphyloma ..	29	213
Choroiditis ..	13	32
Cataract, senile ..	115	223
Cataract, congenital ..	20	19

operations are not available this ancient practice is widespread. From personal observations it seems that two types of operative procedure are practised: dislocation by a needle or thorn is sometimes employed, or manual dislocation by pressure with the fingers. So far as can be ascertained the native manipulators are all Hausa—that is, natives of Northern Nigeria. Acute glaucoma is rarely seen in Lagos. The cases recorded are all the end-result of the chronic simple type of symptomless glaucoma. It will be noted that a considerable proportion of the blindness could be prevented or cured. This investigation shows definitely that no single disease can be quoted as a main cause of blindness in Southern Nigeria.

Monocular Blindness.—The records of this condition were made for comparison and interest. The total number recorded is 948, and the males and females are about equal. It was also found that right and left eyes were equally affected. The sequence of frequency was cataract; leucoma, phthisis, and staphyloma; trauma; local infection; iridocyclitis; and glaucoma.

From this short report it will be appreciated that much remains to be done before comparison of figures and conditions can be made with those of more civilized countries.

I wish to thank the Director of Medical Services, Nigeria, for permission to publish this paper.

Ridley, Harold (1945). *Ibid.*, monograph, suppl. X.

A short article in *La Presse Médicale* of February 2 gives news about medicine in Germany to-day. In Western Germany there are 63,000 doctors as compared with 44,000 before the war. Medical students number more than 22,000 in the universities—in proportion to the population this is more than twice the number in the United States. Doctors are paid very little, and less than half the 17,000 in hospitals are receiving a living wage, so it is scarcely surprising that most of them have to take other jobs and are employed as night watchmen, musicians, and so on. This surfeit of doctors is due partly to the large numbers of refugee medical men and partly to the fact that during the war many hundreds of doctors were trained for service in the Forces. Those most affected are the young newly qualified doctors; the specialists are rather better off. Private patients are rare, and the doctors depend upon State payment for their treatment of insured patients; often they earn less than Post Office employees. There is virtually no freedom for the doctor in modern Germany, who is not even permitted to use his car unless the patient is more than two kilometres away from his home. He is not allowed to refuse to treat a patient. War and its aftermath have meant that Germans frequently fall ill, and the doctors, in spite of their great numbers, work twice as hard as they did before the war for about the same sum of money.

Reviews

HUMAN PHYSIOLOGY

Human Physiology. By Bernardo A. Houssay, M.D., Juan T. Lewis, M.D., Oscar Orias, M.D., Eduardo Braun-Menéndez, M.D., Enrique Hug, M.D., Virgilio G. Foglia, M.D., and Luis F. Leloir, M.D. (Translated by Juan T. Lewis and Olive T. Lewis.) (Pp. 1,118; 499 figures. £5 19s.) London: McGraw-Hill Book Co., Inc. 1951.

Professor Houssay and his colleagues are all professors or directors of physiology, pharmacology, or biochemistry in institutes of research in Argentina. No one section is officially written by any one author; the team takes collective responsibility for every page. The translation is excellent and the illustrations are well chosen, most being taken from the original papers quoted. There are ample and complete references to the original literature, both as footnotes to the pages on the matter under discussion and also at the ends of chapters to the main reviews and monographs.

This book is excellent in its approach to the subject. It is balanced, though it might be possible for a specialist to say that his aspect has not had justice done to it. It is to be compared with the standard textbooks of Starling and Halliburton in this country, and with Best and Taylor's in Canada, or Fulton-Howell's in the U.S.A. It has the great advantage of them all—that it is a first edition; it is new and therefore a comprehensive treatment of the application of physiology to the human subject in a framework and plan cast in the mould of physiology as it was in 1951; it is uninhibited by being written to a plan of earlier years and adapted as different aspects have grown or regressed in importance.

The personalities and authority of the authors are visible throughout, and the book is to be recommended to all physiologists, physicians, and libraries. Its sole disadvantage in England is its price.

A. ST. G. HUGGETT.

ADVANCES IN BACTERIOLOGY

Recent Advances in Bacteriology. Edited by J. H. Dible, M.B., F.R.C.P. Third edition by J. D. MacLennan, M.B.E., M.D., with the assistance of Mary Barber, M.D. (Pp. 325. 14 figures. £1 5s.) London: J. and A. Churchill. 1951.

Nearly twenty crowded years have elapsed since the last edition of this book, and the choice of subjects in rewriting it cannot have been easy. Staphylococcal toxins, the serological classification of streptococci, the typing of diphtheria bacilli, and the evolution of the sulphonamides are among those chosen, although much of the work on them was done in the 'thirties. The central feature of this edition is a group of six chapters on anaerobic infections. Three of these are devoted to tetanus and gas gangrene, and one to botulism: 27 pages may seem an excessive allowance for the last-named in view of its great rarity as a human disease, but it occurs also in animals and birds, and its toxin, as implied in these pages, has been intensively studied as a potential war weapon, defence against which would require universal immunization. Various forms of anaerobic coccal infections of wounds are also described. The authors accept Meleney's distinction between "post-operative bacterial synergistic gangrene" and "chronic undermining burrowing ulcer" and his statement that the streptococci concerned are respectively non-haemolytic and haemolytic. The final chapter in this group is on non-sporogenous anaerobic bacilli and particularly those Gram-negative organisms for which the generic term *Fusiformis* is so inappropriate and *Bacteroides* at least preferable. The author protests vigorously against the neglect of these common pathogens, and the frequent omission of methods of cultivation whereby their presence can be verified. The simple classification proposed is helpful, but it would not enable the bacteriologist

to name all the strains he meets, and in fairness to him it should be said that to identify all such bacteria encountered in mouth and throat sepsis, pulmonary suppuration, bowel lesions and peritonitis, and uterine sepsis is simply impracticable until further study has provided better methods of isolation and stricter criteria of identity. Even so, the task of sorting out these mixtures of delicate and slow-growing organisms may often be too time-consuming for a busy clinical laboratory: this is the real reason for their neglect.

All the illustrations but one are in the chapter on morphology, which tells of additions to knowledge of the structure of the bacterial cell afforded by the electron microscope and by Feulgen staining. There are also two introductory chapters on bacterial physiology, one on the classification of colon and paracolon bacilli and *Shigellas*, and three on chemotherapy. The treatment of this subject is general, including history, commercial production, pharmacology, and clinical effects, whereas perhaps a greater attention to such aspects as species sensitivity and the mode of action of antibiotics on bacteria would be more appropriate here. Viruses are excluded as now entitled to books of their own. It would be easy to suggest other (bacterial) subjects which might have been included had space permitted. Many readers will prefer the exhaustive treatment of a limited number which has been adopted. The authors were faced with a heavy task in trying to present so vast an amount of accumulated knowledge, and have earned our gratitude by discharging it so thoroughly. Most chapters are fully documented, and the number of references independently checked in preparing the text is mentioned as having been 17,000.

L. P. GARROD.

INDIVIDUAL PSYCHOLOGY

Inferiority Feelings in the Individual and the Group. By Oliver Brachfeld. (Pp. 302. £1 5s.) London: Routledge and Kegan Paul. 1951.

The view is widely held among psychiatrists that the idea of the sense of inferiority and of the psychological means by which it can be compensated is too superficial a principle upon which to found a comprehensive system of psychopathology. None the less, the school founded by Alfred Adler has always had a strong appeal for historians, anthropologists, and thoughtful physicians, who have been able to see its application in many forms in their daily work. The Adlerian schema is perhaps a little too obvious and lacking in mysticism and emotionality to become really fashionable. Its acceptance in the English-speaking world has also been hampered by poor translation of the basic literature. This situation has recently been much improved by the teaching of Rudolf Dreikurs and his school in Chicago and by the recent publication of Lewis Way's *Adler's Place in Psychology*.* To these may now be added the book under review. It may be described as a comprehensive and scholarly compilation in which the author traces the origin of the "Gulliver complex" in philosophy and literature.

The author describes the present trend of the Adlerian school and its application to new fields of social psychology. The principle of compensation is followed from Montaigne, through Hobbes, to Pierre Janet, to whom the author gives full credit as the herald of modern psychopathology. The Adlerian system is lucidly presented, and there is a review of the literature in which it has been elaborated and extended. The author's own interest is clearly in the social applications of the theory, and at intervals he suspends the task of presenting the work of others to express his views on the relation of the sense of insecurity to recent political upheaval. In these chapters the reader may feel that Dr. Brachfeld is not giving him a chance to think for himself. The book is, however, an up-to-date and

*London: George Allen and Unwin. 1950 Reviewed in *British Medical Journal*, January 13, 1951, p. 76.

most valuable contribution to the literature of individual psychology, and it will be indispensable to those seriously interested in the subject. The translator, Marjorie Gabain, is deserving of high praise, and the impression is that little of the original has been lost.

ALEXANDER KENNEDY.

DIAGNOSTIC RADIOLOGY

Lehrbuch der Röntgendiagnostik. By H. R. Schinz, W. E. Baensch, E. Friedl, E. Uehlinger, and others. Fifth edition. Part 4: Skelett. (Pp. 514; 674 figures. M. 84.) Stuttgart: Georg Thieme. 1951.

More use is being made of radiography in diagnosis every year, and the appearance of a comprehensive treatise is therefore of the first importance. This volume is a worthy companion for Germany to the great British textbook which has just been completed, and which we recently reviewed. Naturally they follow very similar lines, but in some respects they are complementary, and the German work has several features which deserve attention.

The present volume is mainly on the spine, the skull, and the vascular system. Abnormalities of the vertebrae and their effect on the spinal column are fully described and illustrated. Outline sketches and drawings of sectional specimens make clear the changes which have occurred and their underlying pathology. The results of injury and disease are fully illustrated, and so clearly that they are readily appreciated without reference to the text. In an important section on myelography prolapsed disks and spinal tumours are discussed. The use of contrast media and of gases by injection is fully and exactly described and illustrated.

The article on the skull occupies 240 pages. Injuries and tumours of the skull are fully described, but the sections on ventriculography by Lindgren, and arteriography by Krayenbühl, are of quite exceptional interest. They are illustrated by superb radiographs with clear explanatory diagrams, and they include precise details of the exact technique required in these difficult and important fields. The application of these methods and the diagnosis of cerebral tumours is fully elaborated and finely illustrated, and represents a technical achievement of a very high order.

Radiography of the temporal bones is discussed in a very original and suggestive article. The localization of foreign bodies in the eye is dealt with in a fascinating study in which most ingenious methods are described. In a brilliant chapter on angiography Lindbom describes methods as daring as they are successful and produces illustrations of the results obtained which are really amazing.

In a short review it is impossible to do justice to the vast amount of valuable and original material contained in this volume. It concludes with an ingenious series of outline sketches covering the whole field of differential diagnosis throughout the skeletal system and serving as a visual index to the whole volume. The sketches will be valuable to the teacher and a help to those who do not read German. But such a book as this is worthy of the most careful study and, indeed, will fully reward the effort to be able to read the great language in which it speaks.

HENRY SOUTTAR.

GLAUCOMA

The Glaucomas. By H. S. Sugar, M.D., F.A.C.S. (Pp. 469; 123 figures. £4 4s.) London: Henry Kimpton. 1951.

This small book on glaucoma is a useful and interesting summary of modern views on this perplexing disease. The cognate questions of the physiology of the production, circulation, and drainage of the intraocular fluids and of the maintenance and variation of the intraocular pressure are briefly discussed before the more clinical aspects of the subject—the primary and secondary glaucomas, their aetiology, diagnosis, and treatment by medical and surgical methods.

The amount of recent research directed towards solving the problems of the intraocular pressure and its pathological variations has been enormous, with the result that our views on this subject have changed considerably over the last ten years. The reader will find an adequate presentation of these problems in this book, and, although some will question certain of the conclusions, the general teaching is sound. The author accepts, for example, Friedenwald's unconfirmed claim that Schlemm's canal has an afferent arterial supply and that consequently primary glaucoma is caused by a diminution of the plasma content of this canal owing to sclerosis of these vessels; this results in a failure in osmotic attraction into the canal which would facilitate drainage if it existed. Many authorities would question these assumptions. But on the whole a difficult subject is treated in considerable detail with great fairness and common sense, and new additions to our knowledge of the theoretical problems involved, as well as the immense amount of new techniques in treatment, both with regard to recently introduced miotics and surgical procedures of recent development, are adequately assessed. There is an effective and challenging final chapter on the presentation of popular educational programmes and the conduct of glaucoma clinics to deal with the sociological and administrative problems offered by this disease.

STEWART DUKE-ELDER.

A DOCTOR'S ADVICE

The Doctor. His Career. His Business. His Human Relations. By Stanley R. Truman, M.D. (Pp. 152. £1 4s.) London: Baillière, Tindall and Cox. 1951.

In introducing this book I cannot do better than quote the last paragraph of Dr. Truman's introduction: "The purpose of this book is to interpret for the medical student, resident and practising physician, the professional problems as well as the relationships and responsibilities of the physician to the patient, the public, and his fellow physicians, so they may develop an understanding and a feeling of what is meant by the practice of medicine." The book faithfully carries out this intention. It contains the ripe experience of a doctor trying to convey just the advice he so badly needed when he graduated, and which he failed to get.

He begins by discussing the reasons why students choose medicine as a career, and goes on to the various branches open to the new graduate. As a general practitioner he strongly presses the claims of family practice, but much of what he says applies to any branch of medicine. He discusses the prospects in the various specialties, the pros and cons of town and country, of independent *versus* group practice, and all his opinions are backed up by what he has seen in investigating many kinds of practice in various States. In view of the discussion over here of a possible College of General Practice it is interesting to note that Dr. Truman strongly advises all general practitioners to aspire to membership of the American Academy of General Practice, whose object is "to refocus the attention of the public and the profession on the importance of the general practitioner." One of its requirements from its members is 150 hours of postgraduate education every three years. The Academy is now, next to the American Medical Association, the largest medical organization in the U.S.A.

Shrewdness characterizes every chapter, not least that on equipment of the doctor's "office." Dr. Truman thinks that a general practitioner really established should have a secretary-receptionist, a nurse-assistant, and a laboratory-technician-assistant. It will be evident that the book is primarily addressed to the U.S.A. doctor, but *mutatis mutandis* it would interest any doctor anywhere, especially if he is young. No aspect of practice is left untouched, and the advice obviously comes from one who knows what he is writing about and does it in a most agreeable way. I congratulate the author on striking an original line in a neglected field and feel sure his book will be a success.

A. COX.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY MARCH 15 1952

MEDICAL TREATMENT OF HYPERTENSION

Over the last 100 years the life expectancy of the population has been doubled, so that now the *average* life-span is close to three-score years and ten. This is largely attributable to the decline in infant mortality, improved nutrition, the greater safety of childbirth, the spectacular achievements of surgery, and the successful war against parasites and microbes. Such victories have thrown into relief our failure to deal effectively with rheumatic fever, cancer, atherosclerosis, and essential hypertension, and emphasize the fact that real cures are unlikely to be found until the aetiology of a disease is properly understood. Of the four mortal diseases just mentioned essential hypertension is the most prevalent. According to Master and his colleagues¹ it occurs in 5% of young adults, 30 to 40% of those over 40 years of age, and in 65 to 75% of all persons over 70 (the lower figures apply to men, the higher to women). It is responsible for 15 to 20% of all deaths in people over 50.² Of these deaths about 60% are cardiac, 20% cerebral, and 10% renal.

It is impossible to assess the value of any treatment unless the natural history of the disease is known. Fortunately there have been several excellent long-term studies of untreated patients, such as those by Janeway,⁴ Blackford, Bowers, and Baker,⁵ Keith, Wagener, and Barker,⁶ and Bechgaard.⁷ From these and similar reports certain important facts emerge. First, the mortality rate in men is at least one and a half times that in women except in malignant hypertension, when it is equal. The two sexes should therefore be considered separately. Secondly, the prognosis in any series depends greatly on the nature of the material, and survival rates can be com-

pared only when the patients are grouped according to certain well-defined criteria. In simple terms these are based on the general level of the blood pressure itself and on the reactive behaviour of the ocular fundi, the heart, and the kidneys—four grades of severity being usually recognized. In this kind of grouping not enough attention has been paid to occlusive coronary atherosclerosis as a complicating factor which may alter the whole course of the disease. Thirdly, the fatality rate is about 10% in five years and 20% in ten years for patients in group 1, 20% and 40% respectively for group 2, 40% and 80% for group 3, and 95 to 100% for group 4, being higher for men and lower for women in the first three groups. Lastly, in the unselected series of cases of essential hypertension the death rate is about twice that in the general population.

There is now little doubt that surgical treatment has materially lowered the fatality rate of hypertension.⁸ The question at issue is whether modern medical treatment can do better. The subject was recently discussed at a meeting of the Section of Medicine of the Royal Society of Medicine (reported on page 597 of this issue). Conservative treatment in the past has meant little beyond increased rest and relaxation, avoidance of mental and physical stress, weight reduction, and sedatives. With this kind of regime and the moral support of a doctor about 60% of hypertensive patients remain more or less free from symptoms. It is common knowledge that headaches, fatigue, insomnia, and dizziness occurring in patients with high blood pressure are often due to an associated anxiety state, and psychiatric help (accidental or by design) may be of great benefit. Much of the earlier criticism of surgical therapy was based on the belief that the drama associated with the operation might well remove symptoms by the influence of suggestion. Physicians must apply the same strict criteria to their own results that they advised surgeons to apply. This means long-term studies of the fatality rate in treated and untreated patients, as well as objective evidence concerning the ocular fundi, the heart, and the general level of the blood pressure.

Kempner⁹ has reported that 70% of 777 patients treated by the rice diet showed objective improvement: for example, the T-wave in lead I became upright in 122 out of 224 cases in which it was previously inverted. This is impressive, and Kempner's good results have been achieved by others. The essential feature of the diet is its low sodium content, which must not exceed 0.5 g. daily.¹⁰ It is a mistake to assume that such a diet can be given only in hospital; on the contrary, a good housewife, feeling

responsible for her husband's health, is often more certain of maintaining a strict diet than many hospital kitchens. The cation-exchange resins¹¹ may be expected to play an increasing part in the control of hypertension by dietetic means.

Hexamethonium bromide has passed through its early trials with greater success than was at first predicted. The largest series so far reported is that by Smirk and Alstad,¹² who describe their results in 53 cases, but only 32 of them had been treated for six months or more. Both Smirk and Rosenheim, who spoke at the R.S.M. meeting, prefer parenteral therapy, but oral administration should not be despised. Hexamethonium tartrate may be used when large doses are necessary, so that there need be no risk of bromism. Smirk has emphasized the value of combining hexamethonium with a low sodium diet. This has much to recommend it. For patients on this diet the dose of oral hexamethonium usually lies between 250 and 750 mg. three times daily, and serious variations in the day-to-day response can be countered by altering the diet rather than by juggling with the dose of hexamethonium. There is little evidence to favour the often expressed view that hexamethonium soon loses its effects, that it is of little value for prolonged treatment. On the contrary, there is every reason to believe that the building-up of tolerance is short lived and that the final maintenance dose is known within two or three months, after which it does not have to be increased, although occasionally it may have to be lowered. Side-effects have proved less troublesome than expected and are usually easily countered.

Compared with the low sodium diet and hexamethonium, other drugs for lowering the blood pressure have proved unsatisfactory. This applies to thiocyanate, which is more difficult to handle, too toxic, and less effective; to "veriloid" (discussed by Dr. R. Kauntze at the R.S.M. meeting and in earlier papers¹³), which too often causes vomiting; and to various adrenergic blocking agents such as dibenamine.

The medical treatment of hypertension is likely to remain far from satisfactory until the cause of the disease is known. In the meantime a combination of a low sodium diet and hexamethonium may give the best results; but only a follow-up study over 5-10 years can show whether this treatment is superior to sympathectomy. Owing to the imperfections and troublesome side-effects of nearly all effective treatments and to the benign course of relatively mild hypertension, patients in groups 1 and 2 are probably best left alone, treatment being reserved for those in groups 3 and 4.

CORTISONE AND HYDROCORTISONE

Early publicity, despite the very careful wording of the original reports, quite understandably threw a spotlight on the dramatic rapidity of the relief which cortisone brought to those suffering from the painful and crippling effects of severe rheumatoid arthritis. It is only recently that critical assessments of the potentialities of this extremely important and powerful therapeutic weapon have appeared, and they deserve close study. About six months ago in this *Journal* Dr. E. W. Boland,¹ of Los Angeles, discussed three most important questions about cortisone therapy: Can suppression of rheumatoid arthritis by cortisone be maintained? Will continued administration lead to side-effects necessitating discontinuation? And will continued therapy cause irreparable damage to other organs, especially the adrenals? Enough patients have now been treated over periods of three months to one year or more to give at least partial answers to these questions. The first two are closely related, since the possibility existed that suppression of symptoms could not be obtained without side-effects so serious that reduction below the therapeutic dose would become necessary. Experience has in fact shown that the incidence of side-effects varies with the size of the maintenance dose. Physicians at the Mayo Clinic were able to maintain satisfactory suppression on doses of 75 mg. of cortisone a day or more in 29% of their patients and on smaller doses in the remainder.² Of the patients receiving the larger doses 63% showed side-effects, while only 21% did so on the smaller doses. Men were less prone to these side-effects than women, for in the smaller range of doses they appeared in only 5% of men but in 24% of premenopausal women and 31% of post-menopausal women. With the larger doses the comparable figures were much higher—50%, 72%, and 85%.

In an important report³ published in the *Journal* three weeks ago a team of workers prominent in this country suggest that the significance of these side-effects should not be exaggerated. Facial rounding and irregularity of the menstrual cycle, they point out, are not serious enough in themselves to warrant cessation of treatment. Although the Mayo Clinic figures are high, most of the side-effects are reversible and did not, in fact, lead to discontinuation of the treatment. While, therefore, a careful watch should be

⁵ *British Medical Journal*, 1952, 1, 341.

kept for more serious side-effects such as the masking of an intercurrent infection, activation of a quiescent tuberculous lesion, or diabetes, the appearance of minor complications of treatment should not lead to precipitate withdrawal but only to a greater watchfulness. By carefully selecting their cases Copeman and his colleagues³ were able, within a period of treatment of only three months, to get 17 out of 20 patients back to work on maintenance doses of cortisone without the appearance of serious side-effects.

No one has yet put forward evidence to substantiate fears of permanent adrenal suppression. Freyberg and his co-workers⁴ found that in just under half of their 24 patients treated continuously for at least 100 days the Thorn test showed that adrenal function had been suppressed after withdrawal of cortisone, but this did not prove to be of clinical importance, and in every case recovery occurred within six weeks. The relapse rate after discontinuation is high: in Freyberg's cases 83% relapsed, nearly all within a month, to the condition they were in before treatment began. Since the action of cortisone is purely suppressive, this is to be expected, and it emphasizes that for cortisone treatment to be practical it must be prolonged, unless it is used for other special reasons. These include the treatment of a patient whose arthritis is rapidly progressive, when deformities due to spasm may be corrected during the time that cortisone brings relief. Similarly it may be useful when orthopaedic surgery or manipulation is indicated. But if it is to be used for prolonged treatment of a disease such as rheumatoid arthritis with a long natural history, measured often in years, it is clear that studies over still longer periods are much needed. In addition to relapse of the disease the appearance of a post-cortisone withdrawal syndrome, as recently described by Duthie,⁵ is a serious complication. It occurred in 21% of Freyberg's patients. On withdrawal of cortisone not only does the disease relapse but sometimes in addition severe malaise with depression, fatigability, anorexia, and weakness, combined with the symptoms of relapse, may give rise to a distressing illness. Very gradual withdrawal of the hormone, when this is decided upon for any reason, is an essential precaution.

Since it seems probable that hydrocortisone (Kendall's compound F) is the naturally occurring active principle of the adrenal gland, studies of the effects of this substance may provide the solution to some of these problems of cortisone therapy, and in the opening pages of this issue Dr. Boland does suggest that hydrocortisone may be more effective and, possibly, that its enhanced antirheumatic action is not associated with an increased incidence of side-effects. The

acetate ester of hydrocortisone is not so active as cortisone acetate, but the non-esterified product—hydrocortisone (free alcohol)—appeared to have approximately 50% greater activity than cortisone itself. While these differences may be accounted for in part by the difference in solubility, this may not be the whole answer, especially if the reduction in side-effects is confirmed.

Only very tentative conclusions may be drawn at present about the practicability of prolonged cortisone therapy. It seems clear that rheumatoid arthritis of itself is not an absolute indication for cortisone, and very careful selection of cases is required. But the criteria for selection have not yet been defined. It has not so far been shown that the very early, acutely active disease is the most suitable for long-term treatment, since the dose which may be needed in this type of case has not been established. It remains to be seen whether cortisone treatment maintained for years on end will produce better final results than other modern methods, or whether simultaneous treatment with, for instance, gold will reduce the relapse rate after withdrawal of cortisone. Cautious conclusions are still necessary, but it is certain that these detailed studies of rheumatoid arthritis, in which the disease processes are being carefully observed and, what is more important, being measured, will lead to the development of more effective control in the foreseeable future.

SHERRINGTON

In *A Mathematician's Apology* the late G. H. Hardy had some interesting things to say on age and intellectual activity. Poets and mathematicians, he thought, had often done all their original work before they were 40, an age at which novelists and biologists were only just coming to maturity. Certainly this seems to have been true of Sherrington, though he was clearly from the first a brilliant student. Chance took him to Cambridge rather than Edinburgh, and so to the then most stimulating centre of physiology—particularly of the nervous system—in Britain. Good fortune enabled him to travel in Spain, Italy, and Germany and to work with a number of the leading scientists of the period, an opportunity much rarer for the promising young man to-day than it was in the heyday of Victorian insecurity and freedom. Sherrington grew up at a time when clinical neurology, neurohistology, and the physiological study of both brain and peripheral nerve were all very actively and fruitfully pursued, and not least in England; by such men as Hughlings Jackson, Gowers, and Ferrier.

And it was thus that in 1891, when he was already 34, he was at last ready to start his life's work.

The historical circumstances were powerful, the opportunity of having so many experimental animals probably unique, and Sherrington had a mind that loved precision and order. It was his continual search for the exact word, the completely accurate statement, which made his lectures and his writings difficult and yet at the same time enabled him to see more deeply than his contemporaries and not to take anything for granted. Through his long training he had learned the scientist's supreme wisdom, which is to know how to ask the right questions, how to frame the experiment within the available technical resources so as to obtain an unequivocal and significant answer! The result was *The Integrative Action of the Nervous System*.

He reached his 60th birthday in the middle of the first world war, not long after his transfer to Oxford. Had he died then, or thought chiefly of his impending retirement as so many men might, there could hardly have been an Oxford school of neurophysiology to give so much to the world in training able men and analysing the mechanisms of the spinal reflexes. But he worked on for another 20 fruitful years, and in *Man on His Nature* celebrated his retirement with a scrupulous analysis of the nature of the mind, in which he came to the conclusion that it was something other and more than the integrated functioning of a myriad of nerve cells, a view which commanded great respect and agreement, though here and there dissident opinions and voices were heard.

So another great Victorian genius is gone from us. But his work will endure as long as civilization itself, and his example as a man of science who embraced the humanities will serve as a steadying influence to those who in the contemporary world are trying to challenge the materialism that too facile an interpretation of science encourages.

PROPHYLAXIS AND TREATMENT OF MALARIA

Among the most important of the findings of Fairley and his co-workers¹ which made possible the military successes in Burma and the Pacific in 1944-5 was that the large-scale introduction of treatment with mepacrine abolished blackwater fever. This was observed in both New Guinea and West Africa. In 1942 in New Guinea the use of quinine as a suppressive drug led to chronic latent or recrudescing falciparum malaria, in the presence of which blackwater fever was prone to develop. Later, with the same strain of *Plasmodium falciparum*, Fairley found that 10 gr. daily completely failed to suppress overt attacks or to produce radical cure in experimentally infected volunteers. For this reason

alone the use of quinine as a suppressant and for treatment of chronic falciparum infections should be discontinued. Whether quinine is given by the intramuscular, intravenous, or oral route the danger of blackwater fever is present in patients with chronic falciparum infections who have previously taken this drug. It should not be forgotten, moreover, that in patients severely ill with cerebral malaria caused by *P. falciparum* blood slides may show only scanty parasites, and also that vivax parasites have been mistaken for those of *P. falciparum*. The latter error is particularly likely to occur when thick films are used and where pathological services are ill developed or during epidemics when the practitioner is swamped with work. A further pitfall is the case presenting as overt vivax, ovale, or quartan malaria, but also suffering from a latent chronic falciparum infection without falciparum parasites being present in the blood. The administration of quinine in such cases will cure the overt infection but may precipitate blackwater fever. For these reasons there is much to be said for the avoidance altogether of quinine and the use in its place of one of the synthetic antimalarial drugs.

For severely ill patients in whom speed of action is essential, mepacrine musonate given intramuscularly in doses of 0.36 g. is probably the drug of choice from among those at present available. It produces an effective concentration in the blood 15 minutes after injection and may be repeated in a few hours if necessary. Fairley² stated that chloroquine is probably the most potent schizonticide yet discovered, and elsewhere in this issue Drs. R. N. Chaudhuri, N. K. Chakravarty, and M. N. Rai Chaudhuri report favourably upon it. Scott³ incorporated 400 mg. chloroquine (base) in 500 ml. sterile saline and administered the solution by intravenous drip over one hour. With this technique no serious toxic symptoms developed, and very rapid cures were obtained. Scott considers this to be the best method of treating patients severely ill with falciparum malaria. If, however, quinine is preferred in such cases an intravenous injection will ensure prompter action than one given intramuscularly, and if administered slowly few side-effects will occur. Intravenous quinine injected rapidly may produce a dangerous drop in blood pressure. Intramuscular injections, though followed by less prompt benefit than intravenous, incur the same risk of blackwater fever plus the possibility of sequelae such as abscesses and painful nodes. In falciparum malaria, therefore, they are best avoided.

In the treatment of the vivax attack and of falciparum infections when cerebral symptoms are absent, chloroquine given orally is probably the drug of choice, acting more rapidly than any other schizonticide. Mepacrine in suitable dosage is almost as effective, and experiences in the 1939-45 war showed it to be a schizonticide acting more rapidly than quinine when administered orally.

Camoquine is a new 4-aminoguanoline drug, and as reported by Chaudhuri and his colleagues appears to be second only to chloroquine in schizonticidal properties.

¹ *Trans. roy. Soc. trop. Med. Hyg.*, 1945, 38, 311; *ibid.*, 1946, 40, 105, 229, 621.

² *British Medical Journal*, 1949, 2, 825.

³ *Amer. J. trop. Med.*, 1950, 30, 503.

⁴ *British Medical Journal*, 1950, 2, 7.

It is regrettable that accurate assessment of the relapse rate after the various forms of treatment they used was impossible, as they were working in an area where malaria is endemic and fresh infections common.

Chemotherapeutic prophylaxis of malaria may be effected by drugs acting on the pre-erythrocytic cycles of the parasite or by schizonticidal suppressants. Among the former proguanil occupies pride of place and is the least toxic of all known antimalarials. Tissue forms of falciparum parasites have been shown¹ to be 30 times more sensitive to its action than blood forms, and their growth in the liver to be completely inhibited. The drug is rapidly absorbed and excreted so that daily dosage with 100 mg. is recommended for maximal effect. Although Chaudhuri and his colleagues have found the results of suppression with chloroquine to be better than those with proguanil it should be noted that in these trials the dosage of proguanil was lower than usually advised. It should also be remembered that proguanil given daily will bring about effects on the tissue phases of the malaria parasite unattainable with any other drug, and also that it effectively sterilizes gametocytes. When suppressants are taken without strict supervision malaria is encountered even among those using drugs known to be capable of suppressing the disease completely. In this connexion Bruce-Chwatt and Bruce-Chwatt⁴ found the comparative incidence of malaria among non-Africans in Nigeria to be 10% in proguanil-takers, 21.5% in quinine-takers, 22.6% in mepacrine-takers, and 22.5% in chloroquine-takers.

It is known that proguanil when given in doses too small to be curative may induce resistance of the parasite. Such doses taken by indigenous Malaysians may account for the occurrence there of resistant strains of malaria parasites as reported on page 564 by Drs. T. Wilson, D. S. Munro, and D. R. Richard. It is unfortunate that in their cases irregular dosage of suppressive proguanil cannot be excluded. Experience in the last war showed that suppressive discipline was bad in many units where it had been thought to be satisfactory. A lapse in administration of proguanil may permit growth of the tissue forms of the parasite—i.e., the forms which are most susceptible to proguanil.

Many problems concerning the chemotherapy of malaria remain to be solved, but we now have potent synthetic remedies of tried worth, capable of controlling the disease and of abolishing the risk of blackwater fever. It would seem rational to use them rather than older remedies with their associated dangers.

LEFT HAND, RIGHT HAND

It has long been known that the phenomenon of handedness is not peculiar to man. Consistent individual preferences in the use of one hand rather than the other have been reliably reported in rats, monkeys, and apes, although there is no evidence to suggest that a general tendency to right-handedness exists at any level below that of man. In a recent study of handedness in monkeys, Glee and Cole⁵ describe consistent individual hand-preferences in the performance of a simple manipulative task, but find that the left hand is preferred in

at least as many animals as is the right. This is in full accord with Yerkes's⁶ classical observations on handedness in chimpanzees. In general, hand-preference in primates is consistent for a wide range of manual tasks, although the degree of dominance of one hand over the other varies to some extent in different animals.

The origin of individual differences in handedness is far from clear. Glee and Cole put forward the suggestion that they may be due, in part at least, to a virtually fortuitous asymmetry of neural organization. In studying pyramidal degeneration after lesions of the motor cortex in monkeys they were struck by the considerable variation in the number of fibres which remain uncrossed, and are led to suggest that "... in motor acts which demand greater skill, that hemisphere which gives rise to a comparatively large proportion of crossed fibres has a slight advantage over the other." Variability in the number of decussating sensory fibres which reach one hemisphere through the thalamus is also proposed as an additional cause of lateral dominance. Interesting as these suggestions are, it must be borne in mind that no direct evidence is adduced in support of either hypothesis. Until this is done, the explanation advanced by Glee and Cole must be regarded as wholly speculative.

In man it is generally held that dexterity is linked in some way with the evolution of language and its unilateral representation in the cortex. Indeed, the concept of cerebral dominance has largely arisen in connexion with aphasia and kindred disorders of speech. Recent studies, however, suggest that the relationship of handedness to aphasia may be more complex than has hitherto been supposed. In particular, the incidence of aphasia in left-handed individuals with unilateral cerebral lesions shows considerable variability. Thus Conrad,⁷ in a survey of 800 cases of brain injury, reports on 18 cases in which dysphasia was associated with pre-existing left-handedness. In these cases the lesion was left-sided in ten and right-sided in only seven. Further, the language disorder in all these cases was considerably less severe and long-lasting than in comparable cases of dysphasia in right-handed individuals. Conrad is therefore led to suggest that in left-handed persons there is typically some degree of bilateral representation of speech and that the dominance of one or other hemisphere for this function is seldom as complete as in the right-handed. In his view, left-handedness expresses a less-advanced degree of specialization of cerebral function.

The view that handedness itself is less firmly developed in sinistrals finds some support from a recent inquiry into consistency of hand-usage among healthy adults. Humphrey,⁸ on the basis of a questionnaire distributed among 70 left-handed and 35 right-handed male subjects, reports far greater consistency of hand-preferences in the latter group. Many self-styled "left-handers" are, he believes, more fittingly described as "ambilateral." If the weaker hand-dominance of the left-handed reflects less determinate cerebral dominance, the results of Conrad and others on the incidence of dysphasia among

⁵ *Experientia*, 1951, 7, 224.

⁶ *Chimpanzees*, 1943, Yale University Press.

⁷ *Nervenarzt*, 1949, 20, 148.

⁸ *Brit. J. Educ. Psychol.*, 1951, 21, 214.

sinistrals find a measure of explanation. If cerebral dominance is less firmly established in relation to manual skill, it is not unreasonable to suppose that language will enjoy a similar freedom from rigid unilateral control. This, however, is a hypothesis which will require to be tested by large-scale clinical and statistical investigation. At present, all that can be said with certainty is that the relation of "handedness" to "brainedness" is by no means as clear-cut as has been supposed in the past.

NAILING THE FEMORAL NECK

The multiplicity of instruments originally designed to facilitate nailing the femoral neck remain as a monument to the anxiety with which the operation was originally approached. The elderly patient's further existence without a nail is so unhappy, and the strain of the well-conducted operation so small, that no patient, unless the victim of some urgent crisis such as bronchopneumonia or cardiac failure, should be denied the consolation of the operation. Mr. D. O. Williams and Mr. E. K. McLean, who report their technique in this issue, are not alone in having reduced the operation to its barest essentials, and many surgeons are content to dispense with the hinged gauge and rely on their sense of touch and the radiographic position alone. With the exception of the unavoidable complication of avascular necrosis of the femoral neck, "the bad results of nailing are the results of bad nailing," as Eric Lloyd has emphasized. The success achieved by Williams and McLean is therefore a tribute to their careful technique, though it would have been interesting to know their failures due to necrosis. Even this complication is losing its terrors with the introduction of the plastic femoral head. Other surgeons are not so happy to dispense with the cross-pin. In the aged the nail is almost entirely dependent on the strength of the cortical bone of the great trochanter for its fixation, and if this is thin or widely opened by the pin-starter its grip is very weak. Although the majority of extrusions are due to absorption of the neck or slipping of the pin, nature tends to extrude it even when it is doing its work successfully, and the insertion of a cross-screw, which adds little to the time of operation and is readily removed, has no disadvantages. The pin which is fixed to the nail tends to break if there is any alteration in the angle of the nail and is to be avoided.

With a simplified technique of operation there is room to simplify the post-operative regime, which in most hospitals still drags out a weary three months. Confidence in early weight-bearing, from the surgeon's point of view, is dependent on a good position of the nail, good impaction, and a relatively horizontal fracture line; and from the patient's point of view on the redevelopment of effective muscular control. The surgeon's requirements are apparent from the beginning, and the patient's progress is obvious at the end of the first month. There is no reason why the selected patient should not start weight-bearing at this time—in fact an appreciation of the importance of compression strain on bony union would encourage such attempts. Once such a regime is started it is probable

that the period of bed rest would be further shortened and the more doubtful cases included in the early ambulatory group. Three months' bed rest is a severe test of the fitness of the elderly patient.

A short period of preliminary traction by either a tibial pin or skin traction is a great comfort to the patient, and tibial traction has the added advantage of almost always reducing the fracture, thus enabling the patient to be placed on the operating table without any forcible preliminaries. Such pre-operative treatment is a necessity in hospitals in which an emergency operation cannot be performed. It is true that a short period of waiting will occasionally allow a complication to develop and so prevent operation before the end of the first week. On the other hand, too rapid assessment of the case will probably result in some operative tragedies. Before the emergency operation can be endorsed, it remains for its proponents to prove that it lowers mortality, lessens complications, and produces results as good as those obtained by other methods.

CIBA FOUNDATION

The *Report* for 1951 shows an ever-increasing valuable activity of this charitable trust (which was founded by the well-known Swiss firm in 1947) for promoting international co-operation in medical and chemical research. A series of international colloquia have again been held at the Foundation's house in Portland Place, on such subjects as the visceral circulation, isotopes in biochemistry, and the control of anterior pituitary secretions. Many foreign medical men have been entertained, and particular attention is being given to the promotion of Anglo-French medical relations by the provision of scholarships for British clinical postgraduate students to visit France for short periods (see *Journal*, March 8, p. 555) and for French workers to come here, and by bringing together the editors of the *Lancet*, *British Medical Journal*, *Presse Médicale*, and *Semaine des Hôpitaux* to encourage co-operation and awareness of one another's activities and points of view. The Foundation has also collaborated with the British Council and the Foreign Office (German Section), and provides a home for the Hunterian Society's museum and library and for meetings of the Renal Association. Very close relations with the Royal Society of Medicine have developed, part of its library being temporarily stored in Portland Place, and Fellows of the R.S.M. being able to stay there when the rooms are not required for foreign visitors. The Foundation is building up its own library, chiefly of books and periodicals on endocrinology. Altogether it is coming to occupy a position of key importance in the organization and international relations of British scientific medicine, and the trustees—Dr. E. D. Adrian, O.M., Lord Horder, Lord Beveridge, and Mr. Raymond Needham, Q.C.—and the executive council under them, of which Dr. G. E. W. Wolstenholme is the secretary, are to be congratulated on this valuable achievement after only two and a half years of active work. There was clearly a need for the services the Ciba Foundation is now so imaginatively supplying, and it has a great part to play in future development.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

FOOD-POISONING

BY

JOAN TAYLOR, M.B., B.S., B.Sc., D.P.H.

Director, Salmonella Reference Laboratory, Colindale

Food-poisoning is a difficult term to define, but through common usage it is accepted as meaning an acute intestinal disturbance coming on within a few hours of the consumption of unwholesome food or drink. It is distinguished from other food-borne infections such as enteric fever, dysentery, or primary abdominal tuberculosis by the occurrence of acute gastro-enteritis, though intermediate cases do occur in which the differential diagnosis, particularly from that of dysentery, may cause difficulty.

Food-poisoning may be due to injurious chemical substances, poisonous plants, or harmful bacteria or bacterial products in food. The most usual type of food-poisoning encountered in this country is bacterial in origin, being caused by organisms of the *Salmonella* group. The disease is due to the multiplication of these organisms in the intestinal tract of the host and is known as the "infective type." Food-poisoning due to the ingestion of bacterial products is also fairly common. Some bacteria while growing in food are able to produce toxic substances which on ingestion cause vomiting and diarrhoea; this disease is known as the "toxin type" of food-poisoning. In a report on food-poisoning in England and Wales during 1950, of 3,979 recorded incidents, 2,170 were of bacterial origin (2,021 salmonella infection), 2 chemical, and 1,807 of unknown causation.

Infective Type

The *Salmonella* group of organisms, which now comprises about 250 recognized species, has its natural reservoir in birds, mammals, and reptiles. The organisms multiply in the intestinal tract of man, causing swelling of the mucosa of the stomach and small intestine and the production of a slimy exudate. The mucosa may become ulcerated. In severe cases these lesions may extend to the large intestine, and there may be an accompanying septicaemia. It is believed that a large number of salmonellae must be ingested in order to give rise to clinical symptoms. The organisms are widely distributed in nature and may be transferred to food in a variety of ways: the food may come from an infected animal, or may be contaminated with infected faeces from mice, rats, pets, or other animals; flies may transfer infected material to food; or human carriers may infect food during handling. Carriers sometimes give a history of a recent attack of diarrhoea, but many have had no intestinal disturbance nor have they been contacts of known cases.

As in most instances many bacteria or large quantities of their products must be ingested to cause symptoms, the most dangerous foods are those which are good culture media and which remain at a warm temperature long enough for bacterial multiplication to take place. These conditions are provided by meat dishes, gravies, and soups, particularly if reheated some time after preparation, and also by foods such as custards prepared at low temperatures. Most tinned foods are autoclaved during processing and are sterile, but once opened they are as liable to contamination as other foods. Small tins of ham can be autoclaved, but large tins are pasteurized, as autoclaving results in loss of palatability and changes in appearance. As a result, pathogenic

organisms may be present in tinned ham, particularly in the large tins, and therefore it is wise to keep the tin in the refrigerator to limit multiplication and not to store it for too long. Hens' eggs are rarely infected, but a number of cases of food-poisoning have been traced to the consumption of ducks' eggs. The latter should be placed in boiling water for at least 10 minutes before being eaten and should not be used in the preparation of lightly cooked foods.

A number of other organisms are believed to cause food-poisoning, though their mode of action is unknown. Foods heavily contaminated with faecal organisms such as *Bact. coli* and *Proteus* have caused disease though the organisms themselves have not been shown to be pathogenic or to produce toxins.

One particular type of food-poisoning, caused by the eating of meat dishes which have been cooked the previous day and allowed to cool down overnight, is seen especially in those eating canteen meals, and is apparently caused by the anaerobic organism *Clostridium welchii*.

Toxin Type

Food-poisoning due to bacterial toxins is most commonly caused by the toxin produced by *Staphylococcus pyogenes*. The toxin is formed in the food during the growth of this organism. It is not destroyed by ordinary cooking processes, so that an infected food which is recooked may still cause disease. The food is usually contaminated by a food-handler who may have a septic lesion on the hands or may transfer the organism from his nose or throat via his hands to the food. Food which has been stored before consumption is the most common source of this disease. Ice-cream, cheese, as well as "made-up" reheated foods, are usually the cause. Other organisms such as non-haemolytic streptococci are known to cause the toxin type of food-poisoning. Little need be said about botulism. This toxin type of food-poisoning is extremely rare in Great Britain, only four incidents ever having been recorded. The disease is caused by the toxin of *Clostridium botulinum*, which acts on the central nervous system, causing diplopia, ocular paresis, and sometimes aphasia accompanied by vomiting and constipation.

Chemical Poisons

Food-poisoning may also be due to injurious chemical substances in the food, though such cases are comparatively rare. There are, however, many instances on record in which food has been in containers which have been used for chemical poisons. Some drinks may be contaminated with antimony or zinc as the result of placing acid liquids—for example, lemonades—or acid stewing-fruits in cheap enamel or zinc vessels. The symptoms usually develop very soon after drinking the fluid.

Death Cap

Some foods are poisonous in themselves. Poisoning due to the "death cap" (*Amanita phalloides*), a fungus eaten in mistake for mushrooms, is well known. The mortality rate is high, and children are particularly susceptible. The incubation period is between 4 and 24 hours, when the patient complains of very acute abdominal pain, vomiting, and diarrhoea. The vomit and faeces may contain blood and mucus. In severe cases anuria may follow, and later jaundice and cyanosis.

Allergy

Diarrhoea and vomiting may occur in individuals who have idiosyncrasies to certain foods. These attacks rarely last more than 24 hours. There is an acute onset soon after the food is eaten. Abdominal pain may be severe, but there is no rigidity. Though this syndrome may occur at any age, it is more common in childhood. Sometimes there is a history of other allergic manifestations in the patient or his family. The diarrhoeal stool from these patients usually contains eosinophil cells. The symptoms are cured by the injection of 3 to 5 min. (0.18 to 0.3 ml.) of adrenaline (1:1,000).

Investigation of Suspected Cases

In all suspected cases of food-poisoning it is important that the patient and the suspected food should be investigated as soon as possible, as knowledge of the causal agent may determine the treatment of the patient and the control measures to stop the spread of the disease. The patient's faeces, collected preferably during the acute stage of the disease and before starting treatment, should be sent to a laboratory. Laboratories provide sterile screw-capped receptacles containing spoons with which a portion of faeces may be transferred to the receptacle. If faeces are not available a sterile throat swab should be passed into the rectum, and care taken to see that the swab shows faecal staining; no lubricant or antiseptic should be used. Such swabs, which are suitable for bacteriological purposes only, must be transported to the laboratory before they begin to dry. Vomit may also be sent to a laboratory, although it rarely assists the investigation. Organisms of the *Salmonella*, *Shigella*, and staphylococcal groups are usually readily isolated if no treatment has been started. Suspected food, if available, should always be sent to the laboratory, as the proof that a particular food has caused disease depends on the correlation of the findings in the patients with those in the food. The assessment of the role of any particular organism isolated from food, other than the accepted pathogens such as salmonellae, shigellae, and some types of staphylococci, is extremely difficult.

Clinical Picture
